The amount of manna, therefore, which exudes from the affected leaves is considerable, especially when one takes into consideration the amount of dextrine, a substance which does not exist in the healthy leaves at all.* From calculations made upon a tree of the same age and size, the leaves of the affected lime-tree would have a surface of 240 square metres, or rather of 120 square metres (equal to 145 square yards), since the manna only covers one side of their surface. It would result from this, that on July 22nd, 1869, the lime bore two to three kilogrammes (equal to about 4 lb. to 7 lb.) of honey-dew, reckoned in a dry state.

In the normal conditions of vegetation the saccharine matters elaborated by the leaves, under the influence of light and heat, are distributed through the organism of the plant with the descending sap. In the abnormal state, which determines the production of the honey-dew, the saccharine matters are accumulated at the upper surface of the leaves, either because the movement of the sap is interrupted, or because it is retarded by the viscosity resulting from the formation of dextrine.

The production of honey-dew cannot be due merely to meteorological influences—to the effect of warm and dry summers. No doubt the lime of Liebfrauenberg secreted it during a summer when there were periods of high temperature, accompanied by great dryness; we must not, however, lose sight of the fact that it was a single tree that was attacked by the malady, and that at a little distance there were limes which were perfectly healthy.

It has been supposed that aphides, after having drawn the honey-dew from the parenchyma, discharge it again

* A saccharine substance exudes from the leaves of *Quercus manifera*, in Kurdistan. (Lindley, Bot. Reg., May and June, 1840.) Such a secretion from the oak is more than once alluded to by Latin poets. In the Golden Age—"Duræ quercus sudabunt rescida mella." (Virg. Ec. iv. 30.) Martin remarks (Virg. ii. 36), "It is no uncommon thing to find a sweet glutenous liquor on oak leaves." W. T. D.

* The occurrence of dextrine in the living tissues of plants is at the most hypothetical. Sachs, *Phys. Vég.* (Fr. ed.), 377.

scarcely altered; but it is contrary to the results of analysis to assign it a composition similar to that of leaf sap. It is, however, admitted that certain insects possess the faculty of determining the production of manna. Thus it is to the punctures of a coccus that Ehrenberg and Heimprich attribute the formation of the manna which is still found on the mountains of Sinai.

The manna falls to the ground from the air (that is to say, from the summit of a tree and not from the sky). The Arabs call it *man*, and they, as well as the Greek monks, collect it to eat upon bread in the same way as honey. I have myself seen it fall, collected it, and brought it to Berlin with the plant and the remains of the insect. This species of manna is produced by *Tamarix manifera*, Ehr. As with many other mannas it is the result of the punctures of an insect, which in the present case is *Coccus manniparus*, H. and Ehr. (Berthelot, *Ann. de Chim. et de Phys.*, ser. 3, lxvii. 83.)

The manna, consequently, collected in 1869 at Liebfrauenberg, had not the same origin as the Sinai manna, though it had the same composition. At the time of its appearance upon the lime no insects were observable. It was later that a few aphides were seen glued upon a certain number of the leaves.

I have already stated that after having washed the extremity of a branch, glutinous points were seen gradually to rise; at first scarcely perceptible, they increased each day, so as finally to cover the whole of the upper surface of the leaf. This slow and progressive development of the honey-dew was clearly effected without the intervention of aphides, which did not make their appearance till subsequently, like the flies and bees, either to feed upon the secretion or to pilfer it.

In a subsequent number (Feb. 12th) Harting states that honey-dew is produced by *Aphis tiliæ*, which, living on the under surface of the leaves of the lime, drops its excrement on the upper surface of the leaves beneath. Analysed by Gunning at Amsterdam, it proved to consist of cane sugar. Boussingault remarked, in reply, that the manna of Liebfrauenberg, like the Sinaitic manna analysed by Berthelot, contained, in addition to cane sugar, fruit sugar and dextrine. He added, also, that the leaves of the lime contain considerable amounts of cane sugar almost pure, the origin of which could not be attributed to insects."

[A paper by Goethe (*Œuvres d'Histoire Nat.*, par Martins, pp. 321-328) contains a similar conclusion. He says (p. 324), "I have seen limes, of which the leaves seemed varnished, but where not a single insect was visible. The juice is secreted by the plant itself." Mr. Hanbury informs me that he has noticed the exudation of a saccharine matter from a Canella, and that after repeated cleansings it still made its appearance. He has seen also the occurrence of minute crystals of sugar upon the corolla of the Azalea. De Candolle mentions the same thing in *Rhododendron ponticum* (*Phys. Vég.* i. 238). This is, however, different to the secretion which takes place on leaves, because it is probably merely due to the loss of water from the flower preparatory to fading.

De Candolle remarks that granular secretions are found on the young shoots of the larch, and are collected locally under the name of manna of Briançon; they also occur on *Salix alba*, and upon some other trees. "We cannot affirm," he says, "either that they are a natural excretion, or that they are produced by insects" (*l. c.* p. 240). Dr. Masters states in the 'Treasury of Botany' (p. 38) that a manna-like substance is produced from species of alhagi, and that it is an exudation from the leaves and branches of the plant only appearing in hot weather. Saline secretions from leaves have been more frequently observed. De Saussure states that an accumulation of saline matters at their surface often occurs in garden vegetables, transpiration being impeded, the leaves are ultimately destroyed (*Recherches*, 264, 265). De Candolle found a saline secretion from the leaves of a Reaumuria to consist of carbonates of soda and potash (*Phys. Vég.* i. 237).] W. T. D.

Mr. Douglas, of Loxford Hall Gardens, Ilford, informed us after the meeting that he has some orange trees at the back of a cucumber-house which are frequently affected with honey-dew, though no green-fly ever gets near them, and that he has long been perfectly satisfied that honey-dew is not the result of insect agency.—*Editor of Gardeners' Chronicle.*

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

The Adulteration of Liquors.

Tuesday, April 16th, 1872.

In the course of the speech made when introducing the Bill relating to the sale of intoxicating liquors, the Earl of Kimberley stated that in it he proposed dealing with the adulteration of liquors. He said that nothing was more discreditable than the adulteration now practised; and that there was something so peculiar about public-house beer compared with that procured direct from the brewer, that he had always thought it best to avoid it. He read a description that had been furnished to him of a process of adulteration frequently practised, by substituting a mixture of "foots" and water, together with salt and copperas, for a portion of the beer originally contained in the barrel; and said that honest brewers and publicans, as well as the consumer, would welcome any reasonable provisions for preventing such adulterations.

The Duke of Richmond said that the noble earl had given an account that would almost make a man think twice before touching a glass of beer again; but that he had contented himself with giving an account of the adulteration without saying how he meant to deal with it.

HOUSE OF COMMONS.

The Public Health Bill.

Tuesday, April 16th, 1872.

In answer to a question put by Mr. Rylands, whether there was any probability that the Public Health Bill would be proceeded with on Friday, the 26th inst., Mr. Gladstone said that he would inform the House in the course of a few days.

The Adulteration of Liquors.

Wednesday, April 17th.

In the course of the discussion upon Sir H. Selwin-Ibbetson's Spirituous Liquor Bill, Mr. Watney said that he could not see why the question of adulteration should be dealt with at all in connection with this subject. Adulteration was common to all trades; and it would be more satisfactory if that branch of the subject were dealt with in some such Bill as that brought in by the hon. member for Birmingham.

Dr. Brewer said that he believed adulteration was far more common than was supposed; and it was not always by water, but often by deleterious drugs.

Mr. Greene said that the result of creating a monopoly would be to place the trade in the hands of inferior brewers. It was impossible to adulterate good beer like that supplied by his hon. friend the member for Derby; and the result of a monopoly would be to place such manufacturers at a disadvantage.

Hospital Dispensing.

On Tuesday, April 16th, Mr. Humphreys held an inquest in the Mile End Road, on the body of Anne Charlotte Head, aged 3. The deceased suffered from a cough, and her father, a shoemaker, of 14, Leslie Street, Mile End Road, procured her a mixture from the porter at the London Hospital. He gave her three doses between Thursday night and Saturday afternoon, and at 7 o'clock in the evening she died. Mr. Robert Edward Swyer, M.D., on making a *post-mortem* examination, found that death had been caused by narcotic poisoning. Having tested a portion of the cough mixture in question, he was decidedly of opinion that it was a most improper medicine for a young child, and that a teaspoonful would be sufficient to cause death. In the course of the hearing, it transpired that the mixture was obtained without the knowledge of the doctors, as was often the case. The jury said that this reflected great discredit on the management of an excellent institution; and they were of opinion that the death of the deceased lay at the door of the porter. The coroner said no jury would convict the latter of manslaughter, but he was convinced that great blame was to be attached to him, and that the hospital authorities ought at once to put a stop to so dangerous a practice. The wonder was that such a system of wholesale illegal physicking had not before now brought about disastrous results. The jury agreed that the deceased died from the effects of narcotic poison administered to her inadvertently; and requested the coroner to write to the authorities of the London Hospital to inform them of the circumstances under which the deceased came by her death. The coroner intimated that he would carry out the wish.—*Times.*

Reviews.

A Series of Chemical Labels for use in Laboratories, etc. Published by Mottershead and Co., Manchester.

The progress of Chemistry in Great Britain is much facilitated by the enterprise of a few manufacturers and dealers, who are always prompt in making or importing the chemicals or apparatus discovered or devised by pioneers in the science, or required for educational purposes by its teachers and students. The book of labels before us, all adhesive and easily detached, is apparently intended for the use of analysts and pupils in general practical chemistry, who wish to label their test-bottles in accordance with the unitary nomenclature of modern chemistry; and such workers will thank Messrs. Mottershead for the handy set of labels now issued. For learners in that branch of applied chemistry which is followed by medical practitioners and pharmacists, the series is not so useful. There will apparently be no difficulty in introducing the unitary notation and nomenclature into pharmacy and medicine by simply regarding and speaking of the old salts of potash, soda, etc., as those of potassium, sodium, etc.; and from the remarks of Dr. Quain at the last meeting of the Medical Council, there can be no doubt this course will be adopted in the next edition of the British Pharmacopœia. No inconvenience to prescriber, dispenser, or pupil will result from the employment of such a name as sulphate of magnesium instead of 'sulphate of magnesia,' but the variety of the unitary nomenclature adopted in Messrs. Mottershead's series of labels gives 'magnesium sulphate' for this substance, and similar names for other salts, as 'potassium nitrate,' 'sodium carbonate,' 'copper sulphate.' Both classes of names are varieties of unitary nomenclature, but that which is adopted by Messrs. Mottershead does not accord with the language and practice of medical men and chemists and druggists, while the other to which we have adverted does so most completely.

Proceedings of the American Pharmaceutical Association. 1871. Sherman and Co., Philadelphia.

This substantial volume of six hundred octavo pages is a record of the proceedings at the nineteenth annual meeting of the American Pharmaceutical Association. Our own Conference was founded to a great extent upon the model of this Association, and the general operation of the two bodies is therefore very similar. Meeting in a different town each year, the last convention of American pharmaceutists was held at St. Louis. It was attended by an able representative of our own Society; and those who were present at the pharmaceutical meeting in November will recollect the eloquent tribute paid by Mr. Brady to the excellence and abundance of the work accomplished by our Transatlantic brethren. A glance through the present volume amply justifies this verdict.

The reports issued by different committees working through the year are a striking feature of this Association. The first of these is a report on the progress of pharmacy, giving an abstract of those papers, published either at home or abroad, which have any reference to matters of pharmaceutical interest. It takes the place, therefore, of our own 'Year-book of Pharmacy.' The abstracts here given are somewhat short, but fairly embrace all the important work of the year. The report on adulterations also serves a most useful purpose, by keeping pharmaceutists acquainted with the sophistications likely to occur, and thereby helping to maintain a certain standard of excellence in the drugs and chemicals employed.

The voluntary papers which were read at the meeting are all of a high order of merit, and exhibit much experimental research and sound scientific knowledge. These proceedings constitute a valuable addition to the literature of pharmaceutical science, and we heartily congratulate the members of the American Association on the skill and energy with which they have pursued their labours.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 22. — *Medical Society,* at 8 P.M.
Society of Arts, at 8 P.M.—"Silicates, Silicides, Glass and Glass Painting." By Professor Barff (Cantor Lecture).
London Institution, at 4 P.M.—"Elementary Music." By Mr. E. J. Hopkins.

Tuesday, April 23. — *Royal Institution,* at 3 P.M.—"Statistics and Social Science." By Dr. Guy.
Royal Medical and Chirurgical Society, at 8.30 P.M.

Wednesday, April. 24 — *Society of Arts,* at 8 P.M.—"Nuts, their Produce and Uses." By Mr. P. L. Simmonds.
London Institution, at 12 noon.—Annual Meeting.

Thursday, April 25. — *Royal Society,* at 9 P.M.
Royal Institution, at 3 P.M.—"Heat and Light." By Dr. Tyndall.

Friday, April 26. — *Royal Institution,* at 9 P.M.—"The Modern Greek Language." By Professor Blackie.
Quekett Club, at 8 P.M.

Saturday, April 27. — *Royal Institution,* at 3 P.M.—"The Star Depths." By Mr. R. A. Proctor.
Royal Botanic Society, at 3.45 P.M.

The following journals have been received:—The 'British Medical Journal,' April 13; the 'Medical Times and Gazette,' April 13; the 'Lancet,' April 13; the 'Medical Press and Circular,' April 17; 'Nature,' April 13; the 'Chemical News,' April 13; 'English Mechanic,' April 12; 'Gardeners' Chronicle,' April 13; the 'Grocer,' April 13; the 'Journal of the Society of Arts,' April 13; 'Grocery News,' April 13; 'Food, Water and Air' for April; 'Archiv for Pharmaci og technisk Chemi med deres Grundvidenskaber,' Nov. 1870 to Jan. 1872; 'Gazette Médicale d'Orient' for Feb. and March; Practitioner' for April; 'American Chemist' for March; 'Zeitschrift des allgemeinen osterreichischen Apotheker Vereines,' Nos. 1 to 4 (1872); 'Journal of Materia Medica' for March; 'Pharmacist' for April; 'American Journal of Pharmacy' for April; 'Druggists' Circular' for April; 'Chemist and Druggist' for April 15; 'Répertoire de Pharmacie' for March.

Notes and Queries.

**** In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[312.]—INCENSE.—Try Exodus xxx. 34; or the following from Ure's 'Dictionary of the Arts':—

Santal Wood in powder, 1 lb.
Vitivert, 2 ozs.
Cascarilla Bark, ½ lb.
Gum Benzoin, ½ lb.
Grain Musk, ½ oz.
Powdered Nitre, 2½ oz. HENBANE DWINING.

[314].—PINK OINTMENT.—"Sunderland" wishes to know of a good receipt for Pink Ointment, not the Ung. Hyd. Ox. Rub., B.P.

THE PREPARATION OF PURE ZINC BY ELECTROLYSIS.—M. V. Meyers reports ('Comptes Rendus,' lxxiv. 198) that being in want of pure zinc for the production of hydrogen, he succeeded in obtaining it easily and in an absolutely pure state, by the decomposition of an ammoniacal solution of sulphate of zinc by a galvanic current. The positive electrode used consisted of a plate of zinc and the negative of a copper wire in the form of a T. Upon passing a current from two Bunsen elements through the liquid, the copper is soon covered by a layer of zinc, and a tree of crystals of zinc is formed at the extremities of the wire. The crystals, after removal, should be washed with a dilute solution of ammonia.

POTIO RIVIERI.—In the *American Journal of Pharmacy*, Mr. Louis Cohen gives the following formula for a preparation frequently prescribed by German physicians in the United States under the above title:—

Potass. Carb. depur. ʒj
Acid. Citric. gr. lij
Aquæ ℥ij.
Misce.

GUM SYRUP.—In order to obviate the inconvenience attending the frequent preparation of gum-water required for prescriptions, Mr. Dondé recommends the use of a gum-syrup made as follows:—

Gum Arabic, in coarse powder, 2 lb.
Rain Water, 2½ lb.
Simple Syrup, 6 lb.

Macerate the gum in water, shaking it occasionally for six or eight hours, until completely dissolved; then strain. This gives 3½ fluid pounds of mucilage. Concentrate the syrup to 35° Bmé. [sp. gr. 1·321]; remove from the fire, and let it cool to 60° C. or 70° C., and add the mucilage. It yields 8 fluid pounds of syrup, containing one-fourth its weight of gum. If 1½ ounce of this syrup be mixed with 6½ ounces of water, a clear solution is produced, containing 3 drachms of gum.—*American Journal of Pharmacy.*

CARROTINE FOR COLOURING BUTTER.—A writer in *Dingler's Polytechnisches Journal* (cc. 83) recommends carrotine, the colouring matter of carrots, obtained by exhausting the dried and pulverized roots with bisulphide of carbon, as better adapted for colouring butter than anatto, the carrotine being tasteless and scentless.

ELECTION OF COUNCIL.

Sir,—In reply to Mr. Mayhew, I have no change of views to report since last year, when I took an active part in defeating the proposed compulsory regulations. I am as strongly opposed now as then, to any interference with the details of business not absolutely necessitated by considerations of public safety; and on this point it will be remembered there was literally no case,—I doubt whether even recommendations were necessary except as a sort of peace-offering.

If Acts of Parliament are written in the common language of the people, I do not see how the Pharmacy Act, 1868, imposes upon us any statutory compulsory obligation to frame regulations, which as a body corporate we do not deem necessary.

I am not insensible of the honour of a seat in the Council, but certainly do not covet the distinction. I reluctantly accepted nomination on general principles, at the urgent request of our local association, but I agree with Mr. Schacht that the well-being of the Pharmaceutical Society requires that so far as the expression of opinion on the part of the members can determine the matter of the compulsory regulations, it may be disposed of at the coming election.

JAMES BAYNES.

Hull, April 15th, 1872.

Sir,—Finding there is a generally expressed wish that those who have been nominated for the Council of the Pharmaceutical Society should make known their opinions on one or two pharmaceutical topics, I will, with your permission, do so as briefly as possible.

I am strongly opposed to compulsory regulations, believing a man can conduct his own business with greater satisfaction to himself, and safety to the public, by carrying out his own system rather than being forced by law to adopt the novelties of others; and my objections to legislative interference have been strengthened seeing that not one of the 120 gentlemen who signed Mr. Sandford's circular have replied to the letter of Mr. Proctor, of August, 1871, asking for information.

I am in favour of grants for education to the provinces, as I look to education as the true protector of the public.

The difference between pharmaceutical chemist, and member of the Pharmaceutical Society, and chemist and druggist by examination of the Pharmaceutical Society, seems so slight to me in the public mind, that I should be glad to see the whole of the outstanding chemists and druggists by some wise means brought into the Pharmaceutical Society, so as to form a strong and united body with identical interests, considering this would tend to prevent reckless and hasty legislation by the few to the detriment of the many.

Those friends who urged me to allow myself to be nominated for the coming election of Council of the Pharmaceutical Society, knew my views at the time of asking me, but knowing full well that changes have passed over men's minds on these subjects in a few weeks, I wish to record that if my brother pharmacists consider me worthy of a seat on their Council Board, holding these opinions; if I change them I shall deem it only a common act of honesty to retire at once, rather than continue to sit on the Council Board to oppose the views of those friends who placed me there.

W. W. URWICK.

60, *St. George's Road, Pimlico, London.*
April 16th, 1872.

MISTAKES IN DISPENSING AND PRESCRIBING.

Sir,—In reference to the deplorable case of poisoning by misadventure, for which a chemist's assistant was tried for manslaughter at Devon, as reported in the PHARMACEUTICAL JOURNAL, March 23rd, it might not be out of place to ask your readers if they have ever met with the term Sal. Morph. as applied to the salts of morphia. I have never met with it, and as you justly remark, such a term is not used, although Sol. Morph. (solution) is very common. A similar case of poisoning by which a colonel lost his life in consequence of the chemist's assistant dispensing six grains of one of the salts of morphia instead of six minims of its solution, must be fresh in the memory of most of your readers. It occurred in one of the western towns a few years since, and bears a remarkable analogy to the present case, as the accused on his trial pleaded that he read Sol. Morph. as Sal. Morph., or salt of morphia.

As it is well for all your readers to profit by the experience of others, I will mention a case occurring in my own practice. A prescription was sent to me to dispense, commencing, Morph. Acet. ʒss, and other ingredients to form a composing draught to be taken in two doses! My assistant and myself conned the prescription over, and considered it unsafe to deal with it without further instructions. Fortunately, I had no occasion to apply to the patient, as the writing and initial of the physician were familiar to me. I shall never forget the deathlike pallor of his countenance as I put the prescription into his hand. I thought he would have fallen; he said he had intended it for half a grain; probably he intended ʒss of the solution (P.L.) as it was before the injudicious alteration of the strength of solution of morphia in the new pharmacopœia, which I know prescribers frequently overlook, so that the patients only get half the dose intended.

A Chemist.

Benevolent Fund.

Sir,—My attention having been called to the Benevolent Fund by the circular issued by the Secretary, I will, in the interests of the Society, tell you why I am not a subscriber to it.

Let us first look at the facts and figures as a whole, and then treat them in detail. The present capital is stated to be £12,000, invested in Consols, and yielding a yearly income of £360. The subscriptions and donations for 1871 amount to about £527. Relief granted during 1871: annuities £347. 10s., and temporary grants £77, making a total of £424. 10s. The circular states there are now thirteen annuitants, each receiving £30 per annum, making a total of £390.

"The mountain in labour brings forth the mouse." In a leading article in the Journal of January 6th, the writer rejoices that we have £12,000 capital, which, he says, provides for twelve annuitants, but there are thirteen, and the only way to maintain the thirteenth annuity is to provide another £1000.

I should rather have rejoiced had the money been distributed in past years to relieve the objects for which it was subscribed. After the lapse of thirty years, all that is done with the Benevolent Fund is to relieve twelve people by annuities, and seven by temporary grants, and to rejoice that no more is being spent.

It is time an end was put to this system. The reserve fund ought not in such a society to exceed the amount of five years' expenditure; and with the exception of large sums arising from legacies and special donations, the whole of the yearly income should be divided amongst the deserving applicants for relief.

You appeal to the members for further subscriptions, and say, practically, that out of every guinea you are prepared to apply sevenpence farthing per annum to purposes of benevolence. You are amazed that members are not more willing to subscribe money on these terms. You say you want £1000 to relieve one person with £30 a year. You prefer relieving one person in perpetuity, to relieving thirty-three people with the same sum for one year. You have no faith in the future, and therefore you deal with the money you have as though you were never likely to get any more! But how do you deal with the money which you have? That is my second point. Why is it invested in Consols, rather than in good securities yielding a higher rate of interest? There are Indian Railways with Government guarantee of 5 per cent., which at present prices will yield you more than $4\frac{1}{2}$ per cent., and thus your interest may be increased from £360 to £540; and your annuitants from twelve to eighteen, by a mere stroke of finance. There are other modes of investment, such as Railway Debentures, Mortgages, etc., which the Court of Chancery will tell you are available to trustees, and which will yield as much or more.

Now, then, supposing the present capital were to be left intact, and invested at $4\frac{1}{2}$ per cent.; and the subscriptions and donations for 1872 were to be the same as in 1871, you would have £540 + £527 = £1067, which would give £30 each to thirty people, and leave £167 for temporary relief.

I hope this subject will claim the careful consideration of the members, and that at the Annual Meeting some resolutions will be passed to deal with this fund in some such way as I have suggested, which would, I have no doubt, materially increase the number of subscribers, as it will be felt that whatever sum is subscribed, is applied direct to its legitimate purpose of relieving the distressed.

H. Scholefield.

Newcastle-on-Tyne, April 12th, 1872.

The Council and Provincial Education.

Sir,—The unusually full report which you were good enough to give us of the proceedings of the last Council meeting, must have been read with interest by many, both the subjects discussed being of great importance to country chemists. With regard to the question of grants to provincial associations, I venture to suggest that some such system as that proposed by Mr. Schacht in the Journal of Nov. 18th, 1871, deserves more attention than appears to have been yet bestowed on it; at all events, some system of payment by results. Possibly, for the present, the simplest, if not the best plan might be for the Council to decide annually, as advised by Mr. Frazer, how much it can afford to devote to this object, and then to make to provincial associations grants bearing some definite proportion to the incomes collected locally by these associations; a stimulus would thus be given to local effort, and the principle of helping those who try to help themselves would be fully carried out. It might be necessary to recognize only such associations as could provide suitable rooms, etc., and certain prescribed courses of lectures. It does not appear to me desirable that these proposed grants should be devoted to the reduction of students' fees, but rather to the perfecting of the educational appliances of the association. I feel convinced that provincial Schools of Pharmacy will become necessities of the future, and the development of really efficient institutions is an object worthy of the attention and hearty support of our Pharmaceutical Society.

F. Baden Benger.

Market Place, Manchester.
April 13th, 1871.

Apprenticeship System.

Sir,—Although I cannot hope to add much to the value of Mr. Atkins' remarks upon "Apprenticeship," published in the number for March 30, I am unwilling to let the occasion pass without adding my testimony to the portentous importance of the subject. Mr. Atkins speaks of it as having already given rise to much discussion, both in the columns of the Journal and in the transactions of the Conference, but I am more astonished at the prevailing indifference with which a question so rife with disaster to the future of pharmacy is generally regarded.

It is dangerous to assume the oracle, but I challenge the judgment of ten years hence upon the prediction that the present disorganized state of the apprentice system must end in collapse. Unless it is speedily amended, there must be a break-down in the supply of Pharmaceutists qualified according to law for carrying on the business of pharmacy in England.

A new order of things has, as Mr. Atkins states, deterred many from prosecuting the trade of druggist by dread of the ordeal designed for the protection of pharmacy, but applicable in this country to both, and therein differing from Continental usage. Mr. Atkins also quotes the known and significant fact that the really capable teachers decline the responsibility of teaching; and they will be likely to do so until this responsibility is more clearly defined and restricted within reasonable limits. Men of character do not undertake that which they well know it will be impracticable for them to fulfil. In the meantime Pybus seeks refuge and instruction with Horner, and qualifies himself for dispensing strychnia and prussic acid by grinding cart grease. One does not easily recognise the aptitude of the means to the end, but does Pybus himself appreciate the gravity of the end with sufficient clearness to accomodate himself to the exigencies of appropriate means?

I am not even sure that Mr. Atkins and myself take exactly the same views as to the ultimate shape into which the apprenticeship chaos should resolve, but I cordially agree with him in thinking that pharmaceutists on the one hand, and parents and guardians on the other, need to be educated up to an intelligent understanding of the new relations which masters and apprentices must assume to each other, and to the ceremony of initiation into the art and mystery of Pharmacy.

I must incur the reproach of repeating my own advice, more coherently expressed upon former occasions (for the apprentice difficulty was a subject of anxiety to me as long ago as when I used to discuss it with the late Jacob Bell), and again insist that a pharmaceutical apprentice must in future be dealt with by both parties to the bond as a pupil whose term of instruction is designed solely for his own advantage, and whose services cannot be reckoned as available to any useful extent for his master's profit. Scientific instruction is now absolutely and compulsorily necessary—it must be obtained from the proper sources, viz., from competent professors. Practical and technical experience is also requisite, and the theoretical teaching must therefore be supplemented by the pupil having the run of a pharmacy* where he may become expert in the operations which it will be his duty to perform in his subsequent career as assistant and master. But it is absurd to expect (and hard facts have demonstrated the absurdity) that the master of any pharmacy, with sufficient business to afford these means of instruction, is going to worry himself, or sacrifice an important amount of valuable time in the personal superintendence of an apprentice for a totally inadequate consideration. With genuine sympathy for Pybus and real anxiety about the system which he illustrates, I have quite determined not to undertake him upon these terms, and I believe my judicious friend, Mr. Atkins, has arrived at the same conclusion.

RICHARD W. GILES.

Clifton, April, 1872.

Sir,—The ill-used and ill-educated apprentice!—Such is now the cry in the Journal. No one has hitherto said a word on behalf of the frequently ill-used master.

Most of your correspondents appear to think that the ignorance of the apprentice is owing entirely to the neglect or incompetency of the master. In many cases no doubt the accusation might be justly made. But, in my opinion, the following three causes have also their influences:—

1. The deficiency of the education of the youth previous to his apprenticeship.

2. The placing a youth in a shop where a trade is part druggist, part grocer, part wine-merchant, and part general dealer.

3. The general disinclination of the youth to apply himself, after his business hours are over, to any kind of study whatever.

In discussing these causes, I shall also say a few words in defence of the country druggist.

The first cause admits of easy remedy. Compel every youth to pass his Preliminary examination before being apprenticed; and, like the Apothecaries' Society, let his indentures be recognized at his future examinations. The curriculum of the "Preliminary" will also bear a gradual elevation.

This resolves itself more into a private and financial matter than one coming within the scope of any society's interference. I apprehend that the reason why youths are placed as apprentices to learn various trades is, that they may have such a training as will enable them to get a living for themselves. Many people living in the country in the class of society from which tradesmen are usually drawn, are not in a position to pay heavy premiums in order that youths may be placed in pharmacies as pupils. But as there are different classes in society, so also in the drug trade are there found many classes of businesses and of tradesmen differing widely from each other; and if a youth cannot commence his business life at Savory and Moore's, or Bell's, there is no reason why he should not commence in a humbler sphere. It is thus the miscellaneous druggist becomes to many a useful being, as he enables a youth whose principal drawback is his parents' poverty, to follow a trade upon which he has set his heart. This class of druggist then, who keeps open his shop, not for experimental and fancy pharmacy, but for the vulgar purpose of getting a living, is thus supplied with a youth to assist him. The pharmaceutical instruction may be very limited, but so is the premium. Still there is nothing to prevent such a youth, if he possess ordinary diligence and good conduct, acquiring good business habits and learning how to live. And that youths so instructed have afterwards proved themselves good men of business, and good pharmacists also, we have many living examples now to prove. For the idle and discontented, the guineas premium and elaborate pharmacy would do no better. And as the talented pharmacist is not condemned for his pupil-dunces, why condemn, unheard, the country druggist for his ignorant apprentices? I deplore the ignorance of apprentices as much as any one, but contend that we have no right to condemn *in toto* this class of tradesmen as being the cause of it. The contract of apprenticeship is so frequently prompted by motives of economy, the youth's friends being desirous of finding a home for him for five years and a cheap mode of learning the trade, and the master's object being cheap labour, little scientific knowledge may be imparted; but little if any, in many cases, is even expected. The theory of high pharmaceutical training is at present incompatible with the routine of the generality of country businesses.

In these luxurious times, the temptations of pleasure and dissipation have with many youths greater influence than the inducements to obtain knowledge; and the minds of such youths are more absorbed by the speculations of how they can enjoy themselves in their spare hours, than in any endeavours to improve their mental status. Apathy for intellectual pursuits is quickly succeeded in many cases by a positive distaste for anything like mental labour. The instruction given by the master to his apprentices during business hours, whether such instruction comprise the duties of the shop or the work of the laboratory, will be of little avail for scientific purposes, unless supplemented by systematic and persevering study after the day's work is over. But when the overtures of the master to instruct are declined by the apprentices, as is frequently the case, who is to blame? Apprentices may be dragged through their work, but they cannot be compelled to study.

Thus we have seen that the well-educated schoolmaster-pharmacist, as well as the miscellaneous druggist, may turn out equally ignorant apprentices, without being in any way able to prevent their ignorance.

In conclusion, I cannot refrain from expressing my regret at the tone that has been given, in various contributions to the Journal, to such petty and sensational questions as drudgery, shop opening and closing, shop sweeping, etc. I speak advisedly when I say that such remarks have in many cases an injurious tendency upon the minds of certain apprentices, particularly those of unaccommodating dispositions and indolent habits. They are, upon the slightest grievance, apt to fancy themselves martyrs, brood over their supposed injuries, and as one scabbed sheep makes many, discontent is frequently contagious.

Let a little more of the milk of human kindness be shown in these discussions, and instead of division, let a necessity for fusion be encouraged throughout the trade. To be powerful, instead of uncharitable reflections, we each require the moral support and assistance of the other, though our incomes and habits may differ as greatly as one star does from another in brightness.

A COUNTRY PHARMACEUTICAL CHEMIST.

APPRENTICES: A PLEA FOR WEAK BRETHREN.

Sir,—The Pharmacy Act has had the effect of leaven or ferment on the body pharmaceutical, and is causing to be eliminated from it many morbid elements; and the gaseous and effete matters, which rise to the surface every now and then, in the form of controversies and discussions on questions of law and policy, are of considerable value, inasmuch as they tend to settle such questions on something like a solid basis.

At present there is a lively effervescence on the apprentice question going on in the columns of the Journal, which indicates the meritorious interest felt for the apprentice of the future; but as some of the writers appear to draw the line

* It may be necessary to state that the term "Pharmacy" is understood to comprehend a laboratory and shop, in the latter of which dispensing as well as retail business is performed.

rather too tight, I have given way to a desire to make a few remarks on the subject.

When a man takes an apprentice, he undertakes to teach him the business he himself follows, in the way he himself conducts it, whether the business be that of a pharmaceutical chemist or a tailor; and I hold, that neither in law nor logic is there any other obligation upon him, unless specially stipulated. No man can teach what he does not know; and comparatively few people know the abstract principles of their own business. By way of illustration I will take the tailor. He shows his apprentice how to sew and to make clothes, but he does not enter upon a discussion, every day or so, on the abstract principles of symmetry or of fashion. Then how is the young man to get to know this? Well, by the application of his own thoughts to the subject, by observation and by practice, both of which his master gives him the opportunity to exercise.

Does the medical practitioner teach his pupils anatomy, or physiology, or the abstract principles of medicine?

Are not all medical pupils much in the same position as our own, when their articles expire?

Are the articled pupils of solicitors in any different position?

There are many businesses where two or three assistants, and one or two apprentices are employed. The principal of such an establishment is probably busy all day long, either in the shop or out of it, with business—domestic, social, or municipal. How is it possible such a person can give oral instruction to his apprentices?

We have in our own profession [?] men who are highly cultivated, and follow some branch of science in connection with their business, either for love or profit. The subject may be microscopy, chemistry, or botany. Is such a one bound by any consideration to teach this to his pupil?

I don't think it necessary to continue these remarks further, to enforce the moral or the conclusion. To do that which has often been suggested by writers on this subject, is neither practicable nor beneficial. It is the duty of the apprentice to endeavour to acquire a knowledge of those branches of science that are necessary to enable him to pass the examination he knows he must pass, as well as to enable him to conduct his business satisfactorily. He can do this, by reading during his apprenticeship, to a great extent. If he has the opportunity of attending lectures, so much the better. But in these days of luxury and ease, we are constantly hearing the remark "How can it be expected that young men can begin to study at night after business hours?" I can only say in answer, that "Where there's a will, there's a way;" and it would be much to their benefit if young men would try to find both. The subjection of the will, and the bending of the mind, to the attainment of this object, would be a discipline well worth submitting to.

F. M. Rimmington.

Bradford, April 2nd, 1872.

Pharmacy in the Shop.

Sir,—There is no denying the fact that the practice of pharmacy has not in time past, and does not even now, obtain from chemists and druggists the consideration it deserves, either in an educational or economical point of view. As regards the past, the reason is tolerably plain, for with our predecessors the absence of the requisite skill and knowledge was as general as the possession of it ultimately will be with our successors. Formerly, the trade of a druggist (I think we may here sink the "chemist") was, generally speaking, nearly as mechanical as any other; I say generally, for with the exception of a small minority of clever, practical men, who were chemists indeed, as well as druggists, and who have left behind them an example for all times, the trade was by no means in an advanced position. As regards the present, it is in a transition state, and the druggist of the past is being gradually replaced by the more accomplished pharmacist of the present, so that before long, as a matter of necessity, the practice of pharmacy and the science of chemistry will hold a far stronger position than heretofore, the advantages of which are too patent to call for remark. This communication is more immediately concerned with the present, and especially with the practice of "Pharmacy in the Shop," as distinct from "pharmacy in the Laboratory," so ably treated by a well-known contributor to this Journal, in a recent number. Years ago, when I was a novice in the mysteries of the drug trade, the question frequently occurred to my mind, why certain preparations, easily made, were almost invariably bought instead; this question when framed into words, received, also as an invariable reply, "It does not pay." Well, granted that, under the then existent circumstances, this excuse in a great measure held good, still it cannot apply with equal force now, though many think it does, when we consider the vastly superior education obtained by our present race of pharmacists; and especially since the publication of the present edition of the "Pharmacopœia," which, to a very great extent, has simplified and improved the different processes, thus making the practice of pharmacy intelligible to any one who has the requisite desire, and will take the trouble to make himself acquainted with it.

Apart from the hard and fast question of "Will it pay?" this science, as an educating power, is of much importance, and may be turned to advantage in the instruction of our juniors, as is evidenced by the interest they generally take in any pharmaceutical process out of the common way; this view of the subject has been so ably advocated by the writer before alluded to, that I can safely leave it where it is. The question I wish particularly to bring before my pharmaceutical brethren is, "Does it pay?" I hope to be able to show that it does, while my own experience also answers in the affirmative; of course, I presume that the requisite skill and knowledge will always be brought to bear on the subject. In very few pharmacies indeed is there such a continual round of business as to leave no time for the manufacture of pharmacopœia preparations other than the most simple; in most of them, there is some part of the day, or week, or season, when business is slacker than others, and it is by catching and utilizing these opportunities, that practical pharmacy becomes in one sense a paying occupation. Again, there are very few pharmaceutical preparations that require a long continuance of unremitting attention, so as to prevent the operator being otherwise engaged for even the shortest time; most of those in which I have been concerned, and they are not very few, have permitted me to attend to the requirements of customers and the necessities of dispensing, without any unusual trouble. These operations have, with one exception, all been conducted in the shop, amidst the daily wants of a middle-class pharmacy, giving occupation to many spare hours, and occasional rainy afternoons, besides proving profitable in more senses than the strictly commercial. Another advantage gained by the practical pharmacist is that he is enabled to guarantee the strength or purity of his own preparations when called on to do so. As examples of such as may be made in the shop, while attending to ordinary business, I find in my laboratory book entries of the following, which I select, as being usually bought instead of made at home:—

Liqs. Ferri Perchlor. and Persulph.
Liqs. Potassæ and Sodæ.
Acid. Hydrocyanic Dil.
Antim. Tartrat.
Ferri Phosphas.
Syr. Ferri Iodidi., Ferri Phosph., and
 Syr. Ferri Phosph. tonic (Easton's).
Hydrarg. Cyanid., and Oxid. Rubr.
Spts. Ether. Nitr., and Ammon. Arom.
Ung. Hydrarg. Nitrat.
Emp. Ammoniaci cum Hydrarg.
Oxymel Scillæ.
Exts. Opii and Glycyrrhizæ.
Adeps. ppt. and Benzoat.
Concentrated Infusions, etc.

My apparatus for the manufacture of the above consists of retorts, glass and tin plate, receivers, flasks, Liebig's condenser, sp. gravity bottle, hydrometers, and thermometer, retort stand, Bunsen's and ring gas furnaces, about one dozen evaporating basins or pans, and a few trifling accessories. Gas and water are laid on close at hand. Nothing very costly here, but all efficient and quite handy; no fixtures being used, the apparatus is put away when done with; by the exercise of a little care the breakage is almost *nil*, and it may reasonably be expected that the skill and common sense of the operator would prevent such a catastrophe as a "blow up." The counter space occupied by the above is small, and the *modus operandi* is such that I can see all going on in the shop and attend to the processes at the same time. In the list of preparations above, there is, as I have before stated, an exception: the Liq. Ferri Perchlor. has to be made in the kitchen; the gas furnace and basin being placed under the chimney, all the vapours are effectually carried off. I should advise no one to attempt the manufacture of this article in the shop, or they will most certainly regret it, supposing the shop to contain anything that will spoil, as marble slabs, brass scales, etc. To a practical pharmacist, a laboratory book will be found most useful; in it should be recorded the date and quantity of each preparation made, and if desired, the cost for which it could be produced. From my experience in the manufacture of these preparations, I find that I can save on some 30 per cent., on others 50, and on a few, even a larger per centage of the cost as compared with the prices of wholesale houses, besides being perfectly satisfied that they are correct in every respect, and exactly what they are represented to be.

I have endeavoured to show that the absence of a regular laboratory with its costly appliances need not be a hindrance to the acquirement of a knowledge of practical pharmacy, or an excuse for the absence of such. If the pharmacist has but a moderate amount of room, a few well-selected pieces of by no means costly apparatus, a fair amount of skill and common sense, combined with a reasonably patient temperament, he may hope to go a good way beyond what I have stated, with pleasure to himself and profit to his business.

Liverpool, April 1st, 1872. T. H. Hustwick.

The Sunday Duties of Chemists' Assistants.—To what Extent are they Expedient?

Sir,—I shall esteem it a favour if you will allow the following lines a place in the next issue of the Pharmaceutical Journal. As they pertain to a subject affecting the majority of assistants throughout the country, their insertion may induce others more able than myself to advocate its claims.

To attempt to prove that provision need not be made to meet the requirements of the public at all times in cases of emergency would at once betray a sad unconsciousness of one's duty, but to endeavour to modify the present system, and secure to assistants those privileges which it is right they should enjoy is quite another thing.

The subject at once resolves itself into one or two questions.

1st. Do the requirements of the public render attendance necessary at every dispensing establishment on Sundays? and if not—

2nd. Cannot some plan be adopted whereby such requirements may be met without unnecessary confinement?

The consideration of the first question immediately suggests another. Within a radius of a mile of where I am living, there are no less than twenty dispensing establishments, at each of which (if I mistake not) attendance is given during the whole of the Sunday. I ask is this expedient? Can it be reasonably urged that the probable cases of emergency demand it? and if not, is it not due to assistants upon whom so many duties are incumbent that every possible concession should be made? I believe that the admission of the majority of employers, and the testimony of assistants generally, would show that (as a rule) attendance at one establishment in ten would be quite sufficient to meet every requirement which the just claims of emergency may have upon us; and my own experience differs very widely from that of others if more than 25 per cent. (and here I think I am far above the mark) of the business usually transacted on the Sunday can consistently be called "cases of necessity." How often does it happen that, after remaining in the whole of the day, the actual requirements have amounted to an ounce of delectables and a bottle of soda-water, or they may occasionally extend to a sedative mixture some elderly customer is in the habit of taking every night, and a repetition from a well-known prescription dispensed regularly about twice a week? That such is often the case will be confirmed I am persuaded by hundreds of assistants who, like myself, continually endure the unwholesome confinement that an unnecessary custom imposes upon them. Without adverting to the Sunday cases of "abominable Sunday traffic" carried on under the false pretext of the claims of emergency (where the contents of the till on a Sunday might represent an average day's business), it must be admitted that the present "staying-in" system is to a very great extent unnecessary, and deserves the serious consideration of all interested in the pharmacists' welfare, affecting as it does both employers and employed.

In dealing with the second question, however, greater considerations are involved, and one is reminded that it is far easier to speak of existing evils than to provide a practicable remedy for them. Difficulties will doubtless arise, but I am loth to believe they are insurmountable; and if there is just cause for an appeal against the present unnecessary confinement, surely it behoves those by whom such claims are respected to espouse that cause, and by personal effort endeavour to bring about that reformation which is so sadly needed, and which would be attended with so many privileges.

But can it be done? and if so, how? for after all the whole matter hinges upon this question. I believe that in America it is done, and upon a principle that might be adopted at home. I have been given to understand that provision is made according to the requirements of the neighbourhood. For instance, in a town in which there are, say twenty establishments, attendance is given at perhaps two during the whole of the day, each taking duty in succession; thus, instead of remaining in every Sunday it is only necessary about once in two months, and I would humbly suggest the advisability of endeavouring to establish a similar plan. Of course no uniform method could possibly be adopted, a great deal being dependent upon the position and requirements of the neighbourhood.

It is not difficult to anticipate many objections that would be made, but I fail to see any that can consistently be urged; and since the law requires a standard qualification from every proprietor, it can be no wrong to the public, if, in cases of emergency, they are referred to the registered chemist upon whom the duty then falls.

Much has been done lately towards promoting a more fraternal feeling amongst employers. Let this be not in word only but in deed, and the greatest obstacle is removed. A discerning public would not fail to recognize the justice of our claim. A little forethought would lead to the purchase of known requirements on Saturday, and thus the benefit be shared by all whom it would affect.

To cherish feelings of self-pity or to endeavour to sow seeds of dissatisfaction amongst fellow-assistants, are, of all things, most blameworthy, but by rational means to contend for a concession of privileges that might be so easily granted, deserves the hearty co-operation of all to whom the pharmacists' welfare is dear. Nemo.

G. C.—A beam of common light consists of undulation of the luminiferous ether; these undulations, or wave motions, taking place in all conceivable directions transverse to the line of advance, or the path of the ray. Certain substances, as Iceland spar, only allow of the propagation of these wave motions in two directions, and that in paths lying separate. A beam of common light entering such a substance is bifurcated or doubly refracted, and leaves it as two beams, the undulations of the one being at right angles to the other. In your Nichol prism, provision is made that one only of these shall pass out, the other being shunted off by total reflection. Such a beam as that which passes through the prism is a beam of plane polarized light, and its plane of vibration is the plane of primitive polarization. A little reflection will show that it can only pass through a second Nichol, when its planes of vibrations are in accordance with that of the prism. But the beam of plane polarized light is also capable of being doubly refracted. If a plate of selenite or other doubly refractive substance be interposed in its path, having its axis inclined 45° to the plane of primitive polarization, it will be split into two smaller beams, the planes of which will be at right angles to each other, and inclined at an angle to the plane of primitive polarization. If you fix your eye upon two such vibrating planes, you will see that a second prism would resolve or analyse these into two beams,—the one vibrating at right angles to the original plane, the other in that plane; the one passing through the analyser, the other being stopped by it. It is not possible to go into details here. If you desire to pursue the subject, you will find Dr. Pereira's lectures, delivered before the Pharmaceutical Society, published in the first series of this Journal, Vols. II. and III., and Sir John Herschel's Lectures on Light (*Good Words* for 1865, reprinted in his "Familiar Lectures,") of service. The phenomena can be easily understood if you be familiar with the working of the doctrines of the resolution of forces.

Communications, Letters, etc., have been received from Mr. Scholefield, Messrs. Kay Brothers, Mr. Chipperfield, Messrs. Thorne Brothers, Mr. J. R. Jackson, Mr. W. H. B. Hamilton, Mr. Rayson; Mr. W. Wilkinson, Mr. S. B. Holgate, W. F. C., J. F. F., "Dominus Salus Mea," "A Student."

In consequence of want of space the answers to several communications are deferred.

GONOLOBUS CUNDURANGO.

BY M. TRIANA.

In a note by this celebrated botanist, presented to the Académie des Sciences at the sitting on the 25th ult. by M. Roulin,* some interesting particulars are given respecting this plant, which has recently gained so much notoriety as a new therapeutic agent and alleged remedy for cancer.

The author states that it is not as a remedy against cancer that the cundurango plant formerly figured in the popular medicine of South America; but, that in common with other plants of the same country, the Guaco, the Matos, etc., it was looked upon as an antidote to the bites of serpents. This kind of wound, apparently so trifling, being in most cases followed by death, it is not surprising that the discovery of substances that pass for antidotes should everywhere in popular opinion be surrounded by the marvellous; but it is worthy of remark that in most places the legends bear a resemblance to each other. They generally state that some animal which hunts these reptiles has recourse to a certain plant to heal the wounds and neutralize the venom. Thus, in the Magdalena Valley and in the mountains that bound either side, it is a heron, called the "guaco," that heals itself with the leaves of a composite plant that Humboldt and Bonpland have named *Mikania Guaco*. Still in New Granada, but in the vast plains which extend to the east of the Cordilleras of the Andes, it is a small mammifer that obtains the same result by gnawing the tuberculous roots of an Aristolochia known to the natives under the name of "matos." Lastly, in Ecuador it is the condor which employs as an antidote to the venom of serpents the leaves of a species of *Gonolobus*, called for this reason "cundur-angu," or the vine of the condor.

Some of the species of the genus *Gonolobus* are looked upon by the natives as virulent poisons, and it was in consequence of this belief that its repute as a remedy for cancer had its origin. It is said that a Loxa Indian woman, wishing to poison her husband, perseveringly administered to him an infusion of this plant, but instead of causing his death, he was healed of a cancer from which he had long suffered. It appears to have been this story, become legendary, which suggested to Dr. Eguiguren, physician and brother to the Governor of the province of Loxa, the idea of trying cundurango in cancerous and syphilitic affections. It is asserted that these trials were completely successful, and that, afterwards, the governor himself, having occasion to visit Quito, obtained an equal success with several other persons. The President of Ecuador, Don Gabriel Garcia Moreno, informed of these cures, especially those that had taken place in the hospitals of the city, thought it to be his duty to give them greater publicity, in order to call the attention of the American and European Governments to a discovery which, if confirmed, would give to the native country of the cinchonas a fresh title to the gratitude of the world. Consequently, he distributed to friendly Governments, through their diplomatic agents, ample supplies of the cundurango wood, with a request that they would submit them to the examination of physicians, botanists and chemists.

M. Triana was in this country when the English Government received, and transmitted to Kew for determination, the specimens of cundurango. These were shown to him, but he was unable to recognize by mere pieces of stem a plant that he had never before seen. He was, however, inclined to doubt the anti-cancerous properties attributed to it, remembering that in America the name cancer is applied sometimes to syphilitic or gangrenous ulcers which might be ameliorated or cured by some of the plants contained in the popular medicine of the country. These doubts were, however, somewhat modified upon reading the circumstantial accounts of cases treated in America.

In consequence of the great interest which the subject excited in the Central American States, M. Triana, as a Columbian, thought it to be his duty to make a botanical investigation of this interesting plant; and, although not claiming to speak decisively upon the medical question, he thinks he is justified in saying (1) that some of the symptoms of cases described as being successfully treated in America could only have belonged to cases of cancer; (2) that supposing diagnostic error on the part of the physicians, it is sufficiently well established that serious maladies have been healed by it; (3) that judging by analogy from other asclepiadaceous plants in the genera *Calotropis*, *Cynanchum*, and *Tylophora*, etc., there is reason to suppose that the plant would possess depurative and antisyphilitic properties.

The author acknowledges that in Europe the cundurango has only given hitherto negative results in well-characterized cases of cancer. But he considers that before this experience be taken as decisive it is worthy of inquiry whether the experiments have been made in both countries under the same conditions. Is it certain that the plant in drying does not lose much of its activity? Or is it not possible that in the consignments of cundurango various species of *Gonolobus* have been confounded? Some time since specimens of wood, leaves and fruit had been submitted to him as cundurango, which he had no difficulty in recognizing as belonging to a species of *Macroscepis*, collected by himself in the warm region of Magdalena, and named by Decaisne *M. Trianæ*.

The author states that the plant has close affinity with *Macroscepis*, to which genus however it cannot be referred, in consequence of its corolla, described as being rotate. The same character separates it from *Fischeria*. At Ecuador it was thought to be an *Oxypetalum*, but that genus has smooth fruit, bifid styles and linear petals, characters entirely distinct from cundurango. There remained, therefore, in the group of *Gonolobeæ* only the genus *Gonolobus* itself; and upon examination of the specimens of fruits and leaves at the office of the Ecuador consulate all doubt disappeared, for it was found that the first are follicles with longitudinal ribs, and the latter cordate and deeply emarginated, as in the generality of species of *Gonolobus*. The author, however, considers it be a new species, to which he has given the name *Gonolobus Cundurango*. Many other species of *Gonolobus* found in the tropical zone of America probably possess similar medical properties, but before their respective therapeutic value can be decided, it will be necessary to avoid confounding them. The following is M. Triana's diagnosis of the species:—

G. Cundurango, ramulis sulcatis, petiolis pedunculisque pube gricea indutis, foliis longiuscule petiolatis cordatis sinu lato cuspidatis supra puberulis, subtus cinereo tomentosis mollibus a basi 5-nerviis folliculis ovato-oblongis ventricosis 4-alatis glabris.

* Comptes Rendus, vol. lxxiv. p. 879.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 823.)

X. Asiatic and American Meloeidæ.

The single Asiatic *Meloe*, of which we have any record as an acknowledged vesicant, is the Indian *Meloe trianthema*. Another species has had some reputation in North America, whilst we have memoranda of four that are used in South America. These are all that we are aware of that have enjoyed any repute in ultra-European countries.

Doab Blister-fly, *Meloe trianthemæ*, Flem.; antennæ moniliform, tapering upwards, black; head gibbous, broader than the thorax, inflected, black, minutely punctured; thorax ovate, rounded, shining black, with a steel-blue gloss, minutely punctured; wings length of the elytra, brown, transparent; abdomen, sides of a vivid orange-red, with a line of small black dots, one on each segment; the dorsal line and rest of the body nearly of a Prussian blue; legs black, the tibia terminated with two slender spines, the tarsi of the hinder legs three-jointed, the rest four-jointed. The female is nearly twice the size of the male.—Fleming, Catalogue Ind. Drugs, p. 59, 8vo, Calcutta, 1810.

This fly Dr. Fleming says he believes for medical purposes to be fully equal to the Telini fly (*Mylabris cichorii*). "We are indebted for the knowledge of it," he says, "to Dr. Adam Burt, who discovered it in the fields around Muttra, when he was superintending surgeon of that station in 1809. It abounds in every part of the Doab, and in the districts on the right bank of the Jumna, which is fortunate, as the other species (*M. cichorii*) is less frequently met with in that quarter of the country. The insect appears early in the rainy season. It is seldom seen on the wing, but generally running on the ground, particularly in fields overrun with the common plant *Trianthema decandra*, called by the natives Bis-copra, which probably furnishes it with nourishment, though it is sometimes observed feeding on the flowers of *Solanum melongena*. The orange-red colour of the abdomen, with the black dot on the segments, form a good discriminative specific character."

Dr. Burt having discovered the property which this insect possesses of being a safe and efficacious epispastic, recommended it as a substitute for the Spanish blistering-fly, and by his meritorious exertions, the use of it has been introduced in all the hospitals of the upper provinces. Fleming also adds that during August and September a supply of this insect was gathered sufficient to serve the two medical depôts of Agra and Cawnpore for twelve months.

Narrow-necked Oil-beetle, *Meloe angusticollis*, Say; thorax narrower than the head; elytra and abdomen violaceous.—Say, Entomology, iii. p. 166; Harris, Insects injurious to Vegetation (1862), p. 140, fig. 65.

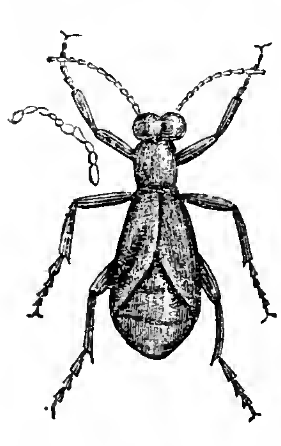

Fig. 21.—*Meloe angusticollis*.

Body dark violaceous, punctured. Head with very deep punctures, an impressed, longitudinal, abbreviated, acute, frontal line; and a transverse, elevated, obtuse one connecting the bases of the antennæ; thorax slender, narrower than the head, profoundly punctured, widest rather before the middle, and narrowed at tip and base. Base emarginate, and slightly margined. Elytra rugulose, dark bluish violaceous. Feet slightly heavy, spines of the tibia and nails ferruginous. Abdomen slightly rugulose, dark greenish, or violaceous; tergum each side black, opaque.

Inhabits Pennsylvania.

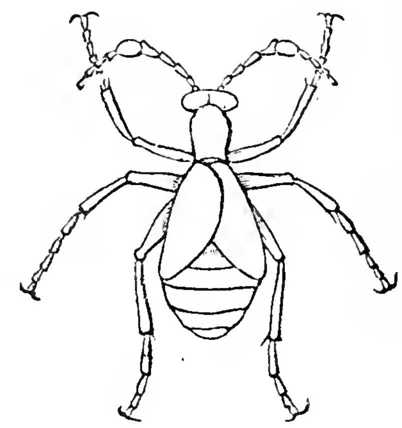

Fig. 22.—*Meloe angusticollis*, male.

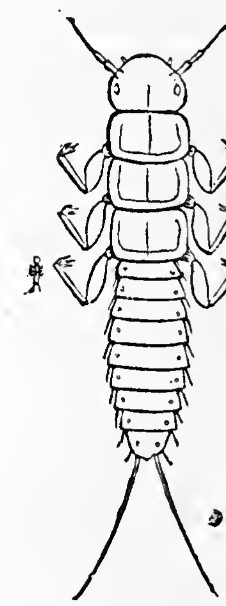

Fig. 23.—Active larva of *Meloe*.

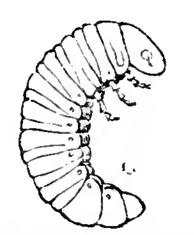

Fig 24.—Second larva form of *Meloe*.

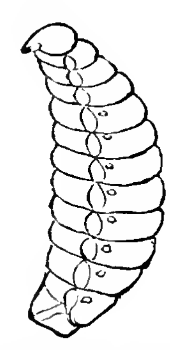

Fig. 25.—Third larva form of *Meloe*.

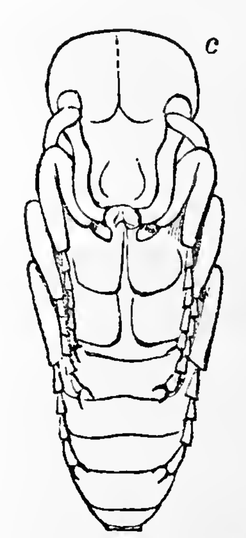

Fig. 26.—Pupa form of *Meloe*.

The remarks of Dr. Packard on this species will serve to illustrate the *Meloeidæ* generally, and explain the changes they undergo:—

"The Oil-beetle, *Meloe angusticollis*, Say (fig. 22, male, differing from the female by having the antennæ as if twisted into a knot; fig. 23, the active larva found on the body of the bee), is a large dark blue insect found crawling in the grass in the vicinity of the nests of *Andrena* and *Halictus* and other wild bees in May, and again in August and September. The eggs are laid in a mass covered with earth at the root of some plant. During April and early in May, when the willows are in blossom, we have found the young recently hatched larvæ in considerable abundance, creeping briskly over the bees, or with their heads plunged between the segments of the body, greedily sucking in the juices of their host. Those that we saw occurred on the humble-bee (*Halictus* and *Andrena*), and various flies (*Syr-

phus and *Muscidæ*), and there is no reason why they should not infest the honey-bee which frequents similar flowers, as they actually are known to do in Europe. These larvæ are probably hatched out near where the bees hybernate, so as to creep into their bodies before they fly in the spring, as it would be impossible for them to crawl up a willow-tree ten feet high or more, their feet being solely adapted for climbing over the hairy body of the bee, which they do not leave until about to undergo their strange and unusual transformations."

(*To be continued.*)

THE THEORY OF THE FORMATION OF CHLORAL.

In the preparation of chloral by the action of chlorine upon alcohol, it has hitherto been generally supposed that the reaction, keeping out of view secondary products, proceeded in two stages, the production of aldehyd being preliminary to that of chloral. And the latter body has been considered to result from the direct replacement of three atoms of hydrogen in aldehyd by three of chlorine.

$$\underset{\text{Aldehyd.}}{\begin{cases} CH_3 \\ CHO \end{cases}} \qquad \underset{\text{Chloral.}}{\begin{cases} C\,Cl_3 \\ CHO \end{cases}}$$

Recent experiments by Wurtz and Vogt appear to show, however, that the changes involved in the operation are less simple. They find that by passing a current of hydrochloric acid gas into a mixture of alcohol and aldehyd, the latter fixes the elements of ethyl chloride, and yields the compound—

$$\begin{cases} CH_3 \\ CH \begin{cases} OC_2H_5 \\ Cl \end{cases} \end{cases}$$

This submitted to the action of chlorine in presence of a small quantity of iodine, furnishes a tetrachlorinated body.

$$\begin{cases} CCl_3 \\ CH \begin{cases} OC_2H_5 \\ Cl \end{cases} \end{cases}$$

which is identical with the compound $C_4H_6Cl_4O$, obtained by Malaguti as a product of the action of chlorine upon common ether, and also with the body recently obtained by Henry by acting upon chloral alcoholate with phosphorous pentachloride.

This tetrachlorinated ether heated with water readily gives chloral according to this equation.

$$\begin{cases} CCl_3 \\ CH \begin{cases} OC_2H_5 \\ Cl \end{cases} \end{cases} + H_2O =$$

$$\underset{\text{Chloral.}}{\begin{cases} CCl_3 \\ CHO \end{cases}} + \underset{\text{Alcohol.}}{C_2H_5HO} + HCl$$

Distilled with sulphuric acid, the same compound gave chloride of ethyl and chloral.

Chloral has, therefore, in these experiments been procured from aldehyd, alcohol, hydrochloric acid, and chlorine; and these are just the substances present in the preparation of chloral by operating with chloral upon alcohol.

The presence of aldehyd among the products of that reaction has been proved by Stas, although it can readily be understood that it can never accumulate in notable quantity, inasmuch as it is at once attacked by the alcohol and hydrochloric acid. The water necessary is supplied, independently of that which may be present in the alcohol, by the reaction of the hydrochloric acid, which has been generated upon the aldehyd and alcohol.

$$\underset{\text{Aldehyd.}}{\begin{cases} C\,H_3 \\ C\,H\,O \end{cases}} + \underset{\text{Alcohol.}}{C_2H_5OH} + HCl = \underset{\text{Monochlorinated Ether.}}{\begin{matrix} CH_3 \\ CH \end{matrix} \begin{cases} OC_2H_5 \\ Cl \end{cases}} + H_2O$$

It decomposes the tetrachlorinated ether, according to the equation already given, into chloral, hydrochloric acid, and alcohol, which last may again react with a new quantity of aldehyd and hydrochloric acid. It is easy to conceive, therefore, that a limited quantity of water, alternately formed and decomposed, may take part in the formation of a considerable quantity of chloral

Wurtz and Vogt also show in their paper (Comptes Rend., lxxiv. 777) that by passing chlorine through a cooled mixture of aldehyd and aqueous hydrochloric acid, or even of aldehyd and water, chloral, contrary to the experiments of other chemists, is formed in notable proportion.

POISONOUS PROPERTIES OF JATROPHA URENS.

BY JOHN R. JACKSON, A.L.S., MUSEUM, KEW.

The following are the authentic details concerning a case of poisoning by this plant, which has formed the subject-matter of a paragraph that has recently been going the round of the papers:—

The occurrence took place in 1823, and the plant in question was raised from seeds sent from Trinidad. It is a small soft-wooded plant having lobed leaves which, together with the younger shoots, are covered with numerous stinging hairs. In the case mentioned above, the wrist accidentally came in contact with some of these hairs, and in a very few minutes the lips became swollen, the face became very red, and the whole system was affected. This was succeeded by faintness and a general suspension of the vital energies, so that for about five minutes the sufferer was thought to be dead, but after the lapse of this time he rallied, the first recollection of recovery being a feeling of relief from the head as if from the removal of a series of weights, each accompanied by a loud sound; sickness succeeded, and in twenty minutes he was again able to stand and was soon quite well.

After this sensational occurrence, the plant was put in a remote corner of the house and attended with great caution, but it soon died. About fifteen years ago another plant was raised at Kew from seed, and this was placed under a wire cage to prevent accidents to visitors. It would seem that Mr. Smith's experience of this plant, though sufficiently alarming, must have been mild by comparison, for we are told that in some persons unconsciousness last for a length of time; the pain and swelling also last for some days, and an itching sensation frequently continues for a much longer period.

The plant is a native of South America, and appears to extend into the Southern States of North America. Mr. Smith tells us that Mr. W. Purdie, who was botanical collector in New Granada for the Royal Gardens, Kew, from 1843 to 1846, spoke of the plant as being a constant terror to his guides during his collecting expedition. In Porcher's 'Resources of the Southern Fields and Forests' it is said that the plant "might be employed like the nettle (Urtica) as a counter-irritant in epilepsies and diseases requiring stimulating applications. The plants of this family furnish generally a stimulating and highly acrid oil, and they should be examined." A reference to the virulent nature of the plant is made at p. 252, Vol. II. of the present series of this Journal.

Another very virulent stinging plant which has been cultivated at Kew is the *Urtica gigas*, or tree-nettle of New South Wales. It grows to a height of 100 or 150 feet, with a tapering trunk which sometimes runs up to nearly 100 feet before branching. The tree is remarkable for the buttresses which are formed with great regularity around its base. It bears dark green cordate leaves, from twelve to fifteen inches wide, the stings upon which are most formidable and even dangerous. The tree was introduced to Kew by Allan Cunningham in 1828, and grew to a height of about six feet, but it died, perhaps from the neglect of the men under whose charge it was placed, and who probably had a natural dislike to it, owing to its excessively dangerous character, and from the fact of several of them having been stung by it. We believe the plant has never since been introduced. The curator was also a victim to this plant, having been stung in the hand; and he describes the effect as one of continued pain in the region of the arm-pit for six weeks or more, which pain became more sensible on the hand being wetted. Another species, *Urtica photinifolia*, likewise a tree abundant in the Clarence and Richmond brush forests is also very poisonous, as are some of the Indian species, such as *Urtica heterophylla*, etc.

A NEW SOURCE OF POTASH SUPPLY.

BY HERBERT HAZARD.

The present sources of the potash supply are rapidly failing; every year the area of the supply becomes smaller, and the product, in consequence of this and the increased demand, becomes more and more expensive. At the rate the country has been settled and the woods destroyed for the past ten or fifteen years, the source of supply in the United States will, in a comparatively few years, almost entirely fail. States which, a few years since furnished large quantities of ashes, now furnish none; wood has become too valuable in the arts to be burned even for fuel. The people as well as the Governments, in the older States, have commenced to discuss the ways and means of perpetuating their hard-wood forests, both as a protection to the land and for mechanical purposes. Soft woods do not yield enough of the salts to pay for working their ashes; hence we are driven to the newly-settled portions of the West and North-west for our present supply, the largest portion of which comes from Michigan and Wisconsin, where the trees are cut down and burned as the readiest means of clearing them from the land. But as the population of these States is rapidly increasing, and railroad lines are being proportionately extended, the forests are brought into more direct communication with the lakes and large cities, thus finding a market for their timber; and the saw-mill will then use up all the surplus trees, which will go into commerce as lumber instead of ashes, as at present. These causes will very much reduce, if not wholly terminate, the present supply from the North-western as they have from the Eastern States.

The forests of the Old World, by care and cultivation still furnish large quantities of potash, but never sufficient for home consumption, therefore this source of supply is not available to us; again, the demand for these salts is constantly increasing, both in medicine and in the arts, two more very cogent reasons why a never-failing source of supply should be secured.

This, it seems, can be accomplished in the following manner:—throughout the Western States large quantities of corn are produced, the cobs of which are now considered of little or no value, yet they may share the same fate as many substances which, though formerly considered worthless, have become new mines of wealth through the aid of chemistry. By the following assays and comparisons, I propose to demonstrate their value to pharmacy and the arts.

One hundred parts air-dried cobs yield, after drying at 212° F., the following results:—

	Cobs.	Ashes.	KCl.	K_2CO_3	Silica, Charcoal, Lime, Iron.	Loss.
1st,	91·70	1·120	·820	·750	·140	·230
2d,	90·95	1·040	·805	·745	·180	·115
3d,	92·85	1·015	·840	·755	·245	·005
4th,	90·94	1·115	·830	·795	·300	·020
Averaging,	91·61	1·072	·824	·762	·217	·093

Or, one hundred parts dried at 212° F., give the following results:—

	Ashes.	KCl.	K_2CO_3	Silica, Charcoal, Lime, Iron.	Loss.
1st,	1·221	·894	·818	·150	·253
2d,	1.143	·885	·819	·192	·132
3d,	1·093	·904	·834	·252	·007
4th,	1·226	·913	·874	·329	·030
An average of	1·171	·899	·836	·230	·105

The cobs were incinerated as thoroughly as possible without the use of nitric acid or other oxidizing agent, the presence of silica impeding the complete combustion of the charcoal. The ashes were assayed by exhausting them with water and filtering off the soluble portion, leaving a residue on the filter consisting of silica, charcoal, carbonate of lime, and a trace of iron. The filtrate was supersaturated with muriatic acid, evaporated to dryness and redissolved in acidulated water, leaving an additional quantity of silica, which was added to the first portion and weighed with it. The solution was then evaporated to dryness and weighed as chloride of potassium, and from this weight the carbonate was calculated.

In volume iv. of Watts's 'Dictionary of Chemistry,' the results of some analyses by Höss are given, from which it appears that ash, oak, elm and willow, which of our most common forest wood are richest in potash salts, yield respectively ·74, 1·50, 3·90 and 2·85 parts carbonate potash in one thousand of wood.

The average yield of one thousand parts of cobs, as shown by the tables above, is 7·62 parts carbonate potash, or nearly twice as much as the best specimens of wood, and from a material which can fill its full measure of usefulness for other purposes before it comes into the hands of the manufacturer of potash.

But the questions may be raised, how can these cobs be collected in quantities sufficiently large to pay for working them, and is the supply sufficiently large to be of any commercial importance? The first question is easily answered, for they are already collected at the shipping-points of the growing districts, where large shelling-mills, capable of running through 500 bushels of ears of corn an hour, are established; here, then, are the places where a supply of cobs may be procured. The figures below will show with what rapidity they accumulate.

A bushel of corn weighs 70 pounds on the cob; a bushel of shelled corn weighs 56 pounds, leaving a balance of 14 pounds cobs to the bushel; and a mill, shelling 500 bushels an hour, turns out 7000 pounds cobs an hour, or equal to 70,000 pounds per working day of ten hours. As many of these cobs as are necessary are used for the purpose of generating steam to run the shelling-mills; the surplus is sold, given away, or even cast out into places to decay. By collecting the ashes from these waste cobs, together with the ashes from the furnaces, it will be readily seen, by reference to the preceding analyses, what large quantities of potash salts may be produced from these now worthless cobs.

That the supply of cobs can never fail, the following statistics will show:—

The corn crop of the United States for 1870, was 1,094,000,000 bushels, of which amount

Illinois yielded	201,378,000	bushels.
Indiana ,,	113,150,000	,,
Missouri ,,	94,990,000	,,
Iowa ,,	93,415,000	,,
Making a total of	502,933,000	,,

in four States alone.

The corn crop of the whole country, for 1871, was 1,100,000,000 bushels, which, at 14 pounds cobs to the bushel, will yield 15,400,000,000 pounds, or 7,700,000 tons cobs, containing an average of three-quarter per cent. pure carbonate potassa. We have the enormous quantity of 115,500,000 pounds of that valuable alkali lost to commerce annually, which, if thrown into trade, would add very largely to the general resources of the country.—*Amer. Journ. Pharm.*

CRYSTALLIZED DIGITALINE.*

BY M. NATIVELLE.

The process adopted by the author for obtaining crystallized digitaline, a magnificent specimen of which accompanied the memoir, consists, in the first place, in exhausting the digitalis in 50† alcohol, instead of water, as ordered in the French Codex. He found that while the product obtained by an aqueous maceration contained chiefly an amorphous principle, soluble in all proportions in water, which he proposed to call digitaleine, the residue, usually rejected as useless and completely exhausted, contained nearly all the active crystallizable principle, together with another very bitter principle, approaching it in its properties, but not crystallizable. The alcoholic tincture so prepared was distilled, and the residue of the distillation concentrated to a weight equal to that of the digitalis originally used. Here the author introduces a modification based upon what is generally observed where several principles exist simultaneously in the same plant, that they exercise towards each other a particular influence, which determines or favours their reciprocal solution in the same liquid. This faculty, however, is manifested chiefly in a concentrated solution, being weakened or completely annulled when the solution is diluted. Thus, a concentrated solution of opium may contain, not only the principles dissolved directly by the water, but also more or less resin carried into solution by the influence of those principles, and which separates when the solution is diluted by a certain proportion of water. So with digitalis, in the concentrated solution that represents the product of evaporation after the alcohol is driven off, is found in solution, not only the principles directly soluble in water, like digitaleine, but other principles, such as digitaline and digitine, which, insoluble themselves, are kept in solution by the influence of the preceding in a concentrated solution. If, however, this solution be diluted by three times its weight of water, a gradually augmenting viscous deposit is formed, which represents nearly the whole of the digitaline, accompanied, it is true, by digitine and colouring matter, but freed from the digitaleine and other soluble principles—according to the author the chief obstacles to crystallization.

In order to extract from the viscous deposit the two crystallizable principles that it contains, it is to be dried in the open air, upon folds of filtering paper, and afterwards treated with twice its weight of boiling proof spirit. The filtered solution, left in a cool place, is quickly covered on the surface with crystals, which also form on the side of the vessel. This goes on for eight or nine days before the liquor is completely exhausted. The crystals are then separated; and after washing with weak alcohol are nearly completely colourless. The digitaline is then separated from the digitine by successive treatment of the crystals with chloroform, evaporating the chloroform, treating the deposit with eight times its weight of boiling 90 per cent. alcohol, adding a little washed animal charcoal, filtering and leaving to cool in a partially stoppered flask. The pure digitaline is then deposited in fine white and shining needles, grouped around the same axis. By this means, the two principles are effectually separated. The part dissolved is intensely bitter, giving a wonderfully intense emerald green colouration with hydrochloric acid, and having such a powerful physiological action that a quarter of a milligram is sufficient to produce the ordinary effects of digitalis. On the contrary, the part undissolved by the chloroform is tasteless, gives no colouration with hydrochloric acid, and exercises no appreciable action upon the organism.

In order to verify the results described in the memoir, the commission followed the process step by step, and succeeded in obtaining a product identical with the specimen accompanying the memoir. They also undertook a series of physiological experiments, the result of which led them to the conclusion that the new medicament appeared to produce effects identical with the other preparations of digitalis, particularly the digitaline of MM. Homolle and Quevenne, but incomparably more energetic, while, from the definite nature of the compound, more constant results follow its use.

* Extracted from the Report by M. Buignet, on behalf of the Commission, recommending the award of the Orfila prize (6000 francs) to the Author.

† The British Pharmacopœia orders rectified spirit.

THE NATURAL HISTORY AND COMMERCE OF SPONGES.

BY JOHN GIBSON.*

Every schoolboy knows that a tree and a dog belong respectively to the vegetable and animal kingdoms; but much older and wiser heads have been puzzled for centuries in trying to settle definitely to which of these two kingdoms sponges belong; and although the great majority of zoologists have now relegated them to the domains of animality, still there are many who hold that they are more at home among the plants, while a third party maintains that their true position is to be found in a *terra incognita*, lying somewhere between these two; that, in fact, the sponge is neither a plant nor an animal, but a living organism in which we find certain characteristics of both. It is curious to observe how opinion on this vexed question has vacillated from the remote past down to the present time. Aristotle, who was the first to make the sponge an object of scientific investigation, speaks of it as an animal. "The sponge," he says, "is a stationary or rooted animal." The same opinion was held by Pliny, who also tells us that in his time some writers divided sponges into male and female. That our earliest biologists should have placed sponges among animals seems somewhat remarkable. The outward marks—which, in those early days of scientific inquiry, were mainly relied on—such as their fixedness, their want of sensation, and their indefiniteness of shape, all seeming to point to their connection with the vegetable kingdom. Aristotle's views held undisputed sway

* Read at the Meeting of the North British Branch of the Pharmaceutical Society, April 18th, 1872.

through the dark ages, or to put it more correctly, the sponge in those times continued to discharge the practical duties of the *toilette*, and no unpractical questions regarding its nature seem ever to have been asked. With the revival of learning in the sixteenth century, however, the question was once more raised; the tide of scientific opinion set in strongly against Aristotle's view, and the sponges were now placed by general consent among plants, and even characterized as the most imperfect of their class. This remained the prevalent opinion down to modern times; thus we find Linnæus, in an early edition of his 'Systema Naturæ,' arranging the sponges among the cryptogamous algæ. About this time, however, Ellis and others succeeded in demonstrating the animal nature of zoophytes in general; again the views of the ancient writers were adopted, and in the twelfth edition of his great work, Linnæus arranges the sponges among animal zoophytes. This opinion has, since that time, been the prevalent one; while, since the publication in the Edinburgh 'Philosophical Journal,' of Dr. Grant's investigations on the structure and functions of the sponge, it may be said to have become almost universal. Regarding the sponge, then, as belonging to the Protozoa—the lowest of the animal sub-kingdoms—let us observe how it plays its humble part in the economy of nature.

The article known to commerce as the sponge, and which consists for the most part of a mass of delicate horny fibres interlaced with each other so as to form a rude sort of net-work, though it belongs to, yet does not constitute the animal. It is merely a framework on which the living part is supported, and corresponding somewhat to the skeleton of the higher animals. Those horny fibres are so arranged as to form regular canals, which permeate the sponge in every direction, and open on its surface in what zoologists term *pores* and *oscula*. The name of *pores* is given to the numberless small openings, while that of *oscula* is applied to those larger apertures which occur at rarer intervals on the surface of the sponge. It will afterwards be seen that the *pores* and *oscula* have very important, though entirely different functions to perform. In many of the sponges also, little needle-like bodies known as spicules are found scattered through the mass. These can be most readily obtained by burning a piece of sponge, when they are left behind, and from the variety of fantastic shapes which they assume, form beautiful microscopic objects. Their presence, however, in any sponge is fatal to its value as an article of commerce. In the living state every fibre of the horny framework is covered over with a coating of gelatinous matter of a brownish-yellow colour, and in other respects somewhat resembling the white of egg. This is the substance known as protoplasm, and which Professor Huxley regards as the physical basis of life. As living sponge is but an immense aggregation of minute bodies of this protoplasm, it may be well to notice some of the results of recent investigation on this substance, and specially as regards its modes of occurrence in nature. It is a true living fluid, for when allowed to escape from the cell in which it is confined, it moves about and gives all the signs of possessing life. It occurs in both the vegetable and animal kingdoms, existing in the former as the inner wall or primordial utricle, which is essentially the vital portion of every cell. In the latter it forms the most important constituent of the blood. Examine a drop of blood under the microscope, and it will be seen to consist of certain bodies known as red and colourless corpuscles respectively, floating in a colourless fluid. Separate a red corpuscle from its fellows, and it makes no motion; it passively assumes whatever shape you may impress upon it. Then place a single colourless corpuscle under the microscope, and, unlike the former, it will be seen to be ever changing its form, like a very Proteus. These colourless corpuscles consist of pure protoplasm. But this substance, which thus seems to carry on a subordinately independent life in the liquid element of our blood, is also found leading an entirely independent existence outside, not only in the aggregated form as in the sponge, but also as a separate solitary creature in the Amœba. This creature is found attached to vegetable growths in stagnant waters, and when looked at through the microscope behaves exactly as did the colourless corpuscle in the blood, or the protoplasm of the inner wall of the cell. It exhibits a constantly changing shape and has thus earned the name of Amœba, from a Greek word signifying change. This creature has been the subject of much and minute investigation, and yet no trace has been detected of what can properly be termed organized structure. It has no mouth, no gullet, no stomach and no intestine, and yet it gets hungry and eats; it grows, and therefore it must digest. How then is the work of nutrition which we always associate with the possession of the above organs performed in a creature apparently so structureless as the Amœba? Simply by its becoming for the time being, all mouth, then all stomach, and lastly all intestine. When the Amœba finds itself in the neighbourhood of something fit for food, it brings itself into contact with it, and then no matter at what part of its body this contact takes place, there it opens up,—an extemporized mouth is formed, and its victim, sometimes larger than itself, is gradually swallowed. Its food being thus engulfed, the creature now takes upon itself the duties of a stomach, and the foreign body is gradually dissolved, until the entire soluble portion is abstracted; the insoluble remnant has now to be dealt with, and the Amœba by virtue of a certain power of contraction which it is believed to possess, assumes the functions of an intestine, presses the effete matter from its interior towards its surface, when the animal again opens up and allows such matter to escape. But to return to our sponge; it has already been said that the gelatinous substance lining its canals is protoplasm. Any one may satisfy himself upon this point by getting a piece of living sponge from the Edinburgh and Glasgow canal, where the *Spongilla fluviatilis* abounds. Taking a thin section of this and placing it under the microscope, the canals will then be seen to be filled with a fleshy substance made up of a number of little bodies. Isolate one of these, and it will be found to exhibit phenomena in every way similar to what has just been described as belonging to the Amœba. Living sponge is thus an assemblage of amœba-like protoplasms supported on a network of delicate fibres. Unlike those creatures, however, the protoplasms of the sponge are fixed, the entire colony remaining permanently rooted; and being thus unable to go in search of food, they are solely dependent for their subsistence on the nutritious particles that may happen to come within their reach; and this bring us to consider the functions of the pores and oscula on the surface of the sponge. Dr. Grant, after long-continued observations, discovered that there was a constant flow of water into the smaller openings or pores, and that there was as regular an outflow of water from the larger apertures or oscula. He also found that the water from the oscula, had in its course through the sponge, been deprived of its oxygen and of its nutritious ingredients; while, on the other hand, it had become charged with the effete materials of digestion. It was thus shown that, by some means or other, water laden with nutritive matter was made to enter by the pores, and that passing along the canals, it surrendered its valuable contents to the little protoplasms arranged along the sides; that sweeping on, it gathered up the effete matter constantly being given off, and then entering the wider passages, its course got turned, and now moving towards the surface was at last ejected from the oscula. The means by which these opposite currents are produced has been the subject of much controversy, but Dr. Grant has shown that in many cases at least they are produced by the action of vibratile cilia. These cilia are minute hair-like bodies found on certain parts of all animals, but occurring in greatest abundance among the lower forms of animal life. They are constantly in motion while the creature lives, and even continue to move for some time after life has become extinct. The cause of this motion is attributed to waves in the protoplasm to which the cilia are attached. Dr. Grant believes that such cilia exist in all sponges, though from their minuteness in certain species, we have not yet been able to discover their presence.

A living sponge may thus be fitly described as a large and populous city, all honey-combed over with innumerable streets and lanes, and whose protoplasmic inhabitants ever sit, like Eastern shopkeepers, out doors, and make their living by picking up whatever treasure fortune may put in their way. Nor are they totally unprovided with instruments for seizing their prey. In common with the Amœba, they have the power of sending out prolongations of their own substance, known as *pseudopodia*, or false feet; and casting these across the watery channel, they lie in wait for the unfortunate animalcule that has just been allured by the ever-waving cilia to enter in at the outside pore, heedless of the shattered remains of fellow animalcules that are being constantly ejected from the neighbouring osculum. With regard to their mode of propagation, the parent sponge throws off little masses of protoplasm, which are taken up by the current passing along the canals, and sent out into the world of waters through the oscula. They float about in the water by means of cilia, specially developed for this stage of their existence, and for some time show considerable activity. Their appetite at this season also appears to be enormous. On this point, Mr. Carter, of Bombay, furnishes us with some interesting particulars. In one case "he saw one of these proteans approach a gelatinous body, something like a sluggish or dead one of its kind, and equal to itself in size, and having lengthened itself out so as to encircle it, send processes over and under it from both sides, which uniting with each other, at last ended in a complete approximation of the opposite folds of the cell wall throughout their whole extent, and in the enclosure of the object within the duplicature. Even while the protean was thus spreading out its substance into a mere film to surround so large an object, a tubular prolongation was sent out by it in another direction to seize and enclose in the same way a large germ which was lying near it. After having secured both objects, the protean pursued its course rather more slowly than before, but still shooting out its dentiform processes with much activity. It took about three-quarters of an hour to perform these two acts." Mr. Dallas, in his work on Natural History, also states: "That not unfrequently combats take place between two of these singular creatures, when, if the size of the combatants be nearly equal, they merely twist about for a short time and then separate, but if there be any great disparity in bulk, the larger one swallows up his antagonist without remorse." After leading this roaming life for a while, they gradually lose their cilia, settle down and get attached to some object at the bottom, where they begin to build up their skeletons, and assume the form of sponges.

(*To be continued.*)

OLIBANUM.

At a recent meeting of the Botanical Society of Edinburgh, Professor Balfour read the following extract from a letter received by Mr. Anderson-Henry from Colonel Playfair, dated Algiers, December 20th, 1870:—"When I was at Aden, Sir William Hooker wrote to me to say, that the tree which produced the *Luban maitee*, or olibanum of the east coast of Africa, was quite unknown to science, and he asked me to try and solve the enigma. It was believed to be a *Boswellia*, certainly not *B. thurifera* of Mutis, and that was all that was known of it. The north-east corner of Africa, around Cape Guardafui, where it was obtained, had rarely been visited by Europeans, never by naturalists; and it was some time ere I was able to get there. However, a report reached us that two men-of-war's crews had been murdered on that coast, and I was sent to investigate the affair in a man-of-war. During my stay on that coast, I directed my particular attention to the gum and resin-producing plants for which it is celebrated (it is the *Thurifera regio* of the ancients). I collected six species, which I sent home in a dried state to Kew, and Sir William Hooker pronounced them all new to botany. Amongst these was the *Luban maitee*, or true olibanum, the most wonderful plant it was ever my fortune to fall in with. It grows *on* not *out* of the polished limestone rock by a sort of intumescence at the base, like a boy's sucker; not a fibre seems to penetrate the soil. The district is almost rainless, yet the tree exudes its fragrant gum in immense quantities. It was not the season to obtain seed, so I did what I could by bringing away live plants, some of which I sent to Dr. Birdwood at the Victoria Gardens, Bombay, and some I planted on the hills at Aden in as nearly their natural condition as I could. Of these, a number succeeded; and they have at length flowered and seeded. A very small quantity of the seed reached me from Aden a day or two ago; and this I share equally between Hooker, you, and myself. The problem will be to get it to grow. It will require, of course, great heat; but in its native climate it gets very little moisture. I also send you a small specimen of the gum produced by the tree, which I actually gathered myself on the spot, and have kept by me ever since. It bears a great resemblance to the gum dammar of commerce."

COTTON SEEDS.

BY HORATIO N. FRASER.

From the time when cotton was first cultivated in the United States until within a few years, the lint or fibre was the only part used either in medicine or the arts; the seed, or all that part not used for re-planting, was considered as having no value, and was looked on only as an incumbrance. Since these seeds weighed nearly twice as much as the part formerly used, it became the subject of thinking men's experiments—how they could be turned to some use; and the results of these experiments have lead to the discovery and subsequent usage of the various products obtained therefrom.

A chemical analysis of the seeds demonstrated that a large percentage of a fixed oil could be produced from them, and not only that, but that the kernel might be advantageously used for food for animals. This latter was tried some years ago, but led to bad results; for even the best gins which were invented could not separate the lint entirely from the seeds to which it adhered, consequently this insoluble matter, with the hulls, formed hard masses in the stomach, and produced even fatal effects from the irritation of the membranes of the intestines. But, to obviate this, hullers have been made which decorticate, or remove the hull, with the adhering lint, entirely from the kernel. This is almost an invaluable invention for the planter; for, when we consider the millions of pounds of cotton which are annually produced in the Southern States, and also that the weight of seed is double the weight of the other portion, then we may be able to estimate the value of these seeds, when turned into nutritious food for stock.

Since small hullers have been introduced on many of the plantations, the planters are enabled to hull their own seeds. These are thrown into the top of the hullers, and first come in contact with knives, which cut the hull; then they are passed through sieves, by which process the kernel and hulls are separated. The kernel is divided into two portions; the first is that part which has been broken or cut by the knives; this is ground to make the meal used for feeding, and constitutes one-third of the whole weight of kernel. The remaining two-thirds come out whole, and are sold for other purposes. This meal has been found to be as rich in flesh and fat producers as linseed meal for stock, and supersedes the use of it in the cotton-growing States. The hulls are piled in heaps until they arrive at the right state of decomposition to be used as a fertilizer, for which they are well adapted, being rich in the phosphates and lime characteristic of substances used for this purpose. The seeds contain a fixed oil to the amount of about thirty-seven per cent. of the weight of the kernel, most of which is obtained by expression.

At the factory on Long Island, which the writer visited, the seeds are bought with the hulls on, although the whole kernel is generally bought directly from the planter. These are first thrown into a gin, which separates some more of the lint. This is packed in bundles and sold for ordinary cotton batting. From this they are conveyed to the hullers and undergo the decorticating process. The kernel is then carried by an elevator to a box, which feeds two large iron rollers, converting it into meal; the meal is put into a large vessel heated by steam, to render the oil more fluid, and then is put between iron plates, which are forced together by hydraulic pressure, which presses out nearly all the oil and some mucilage. About eight per cent. of oil is left, which cannot be removed except by solvents. This oil, as then obtained, is of a handsome dark wine colour and sweet taste. This then undergoes the purifying and bleaching process, which is kept a secret by the manufacturers.

The purified oil is either a golden yellow or white colour. An oil is also produced by chilling the purified oil, and expressing, to obtain a variety almost free from stearine, called by the manufacturers "winter oil," from the fact that cold will not thicken it.

This oil is used extensively in the arts, chiefly to adulterate and substitute higher-priced oils. Cheap paints are ground in it, and it is used to a certain extent to adulterate linseed oil; but being a non-drying oil, only a small percentage could be used.

It is also used for adulterating sperm oil for burning, and for mixing with lard oil. The most practical way to detect these is to heat the suspected oil with distilled water; separate the water and add a solution of subacetate of lead. If it contained cotton-seed oil, a white precipitate will be formed, on account of the presence of mucilage, which is always found in this oil. If the sperm or lard oil is pure, it would be indicated by the absence of any milkiness.

It is also used to adulterate olive oil, and chemistry has found no practical mode by which they can be definitely distinguished apart.

A soap has been made of the residue left after refining. It is of a more or less dark brown colour, and disagreeable smell. It is used in the laundry, and sells from three to seven cents a pound, according to quality. It was also attempted to make a soap from the white oil. This, when first manufactured, is of a handsome white colour, but after standing some length of time it becomes dark, and finally almost black. It is not made now.

It is used to the amount of ten per cent. in making fancy soaps, to give them a good lather, for which the oil is said to be the best known; but even in this small amount the odour of the rancid oil can be detected.

The hulls are used for fuel in the factory, and the greater part of the cake-meal was sent to Europe, the farmers of this country, at that time, not being generally acquainted with its properties. It sold for about thirty dollars a ton.

A few years ago, the oil was noticed in the journals in connection with preparations of pharmacy, to be substituted for oils in liniments and ointments, for which it is adapted by its properties as an emollient, but nothing definite was arrived at. Being cheaper than even the commonest grades of olive oil, and resembling it so much in its behaviour, it is peculiarly fitted for the preparations of the pharmacopœia in which the olive oil is used. Mixed with aqua ammoniæ in the officinal quantities for "Liniment. Ammoniæ," it makes a product which has all the essential properties that are indicated by the olive oil, and has the advantage of not forming so thick a mixture, thereby making it more convenient. In the "Lin. Camphoræ," it seems to serve exactly the same purpose as the officinal oil.

Lead plaster made with the cotton-seed oil has been substituted with advantage for the officinal, and has been used to mix with it to the amount of fifty per cent. by some manufacturers of the plaster. This, made with the cotton-seed oil alone, forms a handsome, light coloured plaster, apparently equal in all respects to the English, with the exception that it does not become hard enough to keep its shape, in the usual form of selling it. But when mixed with olive oil in equal proportions, this difficulty is entirely overcome.

The cost of the plaster made with the cotton-seed oil, using the best English litharge, is twenty cents per pound. This difference in the cost, combined with the practicability of using it, will recommend it to the more careful examination of druggists who deal extensively in this preparation.—*Amer. Journ. Pharm.*

MEETING AT LEEDS.

A Meeting of Members of the Pharmaceutical Society resident in Leeds, was held in the Library of the Chemists' Association, on Monday, 22nd inst.; Mr. Edward Brown, President of the Leeds Chemists' Association, in the chair.

The Chairman said that it had been their custom for the past few years to meet for the purpose of consultation, upon the important question of selecting representatives at the annual election of members of Council. He believed that the desirability of this mutual consultation was never greater than at the present time. A glance at the past disclosed the fact that no less than three Defence Associations had been formed amongst chemists and druggists to oppose aggressive legislation threatened towards our body. It was now made pretty plain that Government did not entertain the inflexible determination to enforce such legislation, as it had been loudly asserted was the case.

But the real danger lay in the conduct of some who ought to be their friends, and the combination to which he had alluded was rendered necessary in order to deliver them from such friends. Whilst the meeting would doubtless receive with due respect the results of any deliberations on the same question from their brethren elsewhere, he was fully aware that it would do so in an independent spirit, and consider the whole question upon its merits. The desirability of united action amongst those holding similar opinions was very clear, and he would ask the meeting to consider whether the candidates put forward by the Defence Associations would compare favourably, on general grounds, with the other candidates. Personally, he believed they would do this.

The following Resolutions were unanimously adopted:—

1. That this meeting of Members of the Pharmaceutical Society, having considered the List of Candidates for the new Council, resolves that the list of 14 names proposed by the United Defence Associations is deserving of its cordial support, and hereby promises the same.

Moved by Mr. E. Thompson,
Seconded by Mr. W. Smeeton.

2. That the Chairman and Local Secretary be authorized to sign, on behalf of this meeting, a recommendation of the said List.

Moved by Mr. J. Day,
Seconded by Mr. E. Yewdall.

The thanks of the meeting were voted to the Chairman.

The Pharmaceutical Journal.

SATURDAY, APRIL 27, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACY IN THE SHOP AND APPRENTICES.

Two subjects have now for some time been discussed side by side, in the columns of this Journal, both of them extremely important in their bearings on the future welfare of the pharmaceutical body, and also having a more intimate relation to each other than has yet, perhaps, been claimed. The recent discussion on the apprenticeship question, having had its origin in the large proportion of candidates failing to pass the Preliminary Examination, turned rather upon the necessity of exacting an educational test from apprentices, previous to their being bound, than upon the best method of imparting to them a sound technical education after they have entered the business. As regards the former point, it is gratifying to find a very general recognition of the principle that no one who has the welfare of pharmacy at heart should receive an apprentice, on any terms, until he has satisfied the present very moderate requirements of the Preliminary Examinations.

But it must be evident that the exclusion of unqualified candidates from among the apprentices is even of less importance than the adoption of adequate means of educating those who are accepted. It is, therefore, to be regretted that the subject broached by the President of the Pharmaceutical Society, with the special object of pointing out how a more general preparation of galenicals by pharmacists would conduce to the education of their apprentices, has been argued more particularly from the point of view whether it would pay, and as to the amount of immediate benefit that would result to the master.

These are matters that will perhaps be decided upon variously, according to special circumstances, and they may well be left to individual judgment; but in the interests of those entering upon the business of Pharmacy, the home preparation of galenicals and chemicals is at the present time especially deserving of further consideration from a different point of view by those who still take apprentices.

It is true the changes that have occurred in our social relations during late years, especially in large towns, have done away with much of the domesticity that formerly brought the master, as a teacher, more intimately in contact with his apprentice. Moreover the enhanced facilities of communication, together with the increased use of machinery, have enabled manufacturers to offer inducements to the pharmacist to buy many of his preparations ready made, and these, with a variety of other circumstances, have tended much to develope an inclination to shift the burden of educational responsibility almost entirely upon schools of pharmacy and the apprentice's own efforts. A recent correspondent speaks of the majority of provincial pharmacies, as being places where the "master's "time is fully occupied with the multitudinous affairs "of the shop;" and, while freely acknowledging that it is the master's duty to see that the pupil receives a fair share of practical tuition, he is of opinion that "this may be accomplished by a supply of experi-"mental apparatus, and an allowance of extra time "each week for the student's use."

We fear that even this is far in advance of what, in very many cases, is acknowledged as the duty of employers towards their apprentices, or is at any rate practised in all cases. But even if the apprentice were always able to study for a term at a school of pharmacy, or if professors were—

> "Glad to turn itinerant
> To stroll and teach from town to town,"

such a system would still leave a deficiency that could be supplied by no person so well as by the apprentice's employer. Attendance at systematic courses of lectures and the study of scientific principles should certainly be regarded as necessities for the pharmacist of the future; but we believe the shop must ever be the chief school of practical pharmacy; if it be connected with a laboratory, so much the better. No amount of book or lecture knowledge, although supplemented by experiment, will supply that experience which is to be gained in the habitual preparation of the pharmacopœial compounds; and it is evident from the testimony of several of our correspondents that such preparations can frequently be made at home with advantage, both in price and quality.

But were it otherwise, and did it entail a cost upon the employer, the necessity appears equally plain for all who incur the responsibility of taking apprentices. It now is the clear duty of every pharmacist to do all he can to raise the status of his calling, and in no way can the individual be so influential in that direction as by turning out a well trained and thoroughly taught pupil. Of course, for a long time there will exist those who, untaught themselves, are unable to teach, and by whom apprentices will be taken to supply the places of mere shopmen and porters. But each year the proportion of qualified men will increase, and it will behove them to keep up the standard of education, not only by exacting from their apprentices the preliminary test, but also by securing a payment in the way of premium that shall be an equivalent for the time, labour, and money requisite for giving their apprentices such technical instruction as will fit them to take honourable and useful positions in the calling they have chosen.

EARLY CLOSING IN THE METROPOLIS.

It is satisfactory to be able to report that this movement, to which we referred three weeks since, is steadily progressing. Many laudable attempts in the same direction have previously been made, but from a want of co-operation between the employers and the assistants, with whom they have generally originated, but little success has hitherto been attained. On this occasion, however, the employers have taken the lead, and the results are, so far, very gratifying. Already nearly all the chemists in Oxford Street, Bond Street, Piccadilly and Conduit Street have commenced to "educate" the public into the habit of sending for their medicines in proper time, and with that object they have agreed to put up their window-shutters at 8 P.M. and their door-shutters at 9 P.M.

We direct attention once more to this movement, the more readily, since, there being no organization, —no treasurer, to collect subscriptions, and no secretary,—the spontaneous adherence of the London pharmaceutists is required, each being left to adopt such hours as may suit him best. We think we are justified in saying that, on the part of the assistants, there will be an effort made to prevent the interests of the employers suffering from the change.

THE ANNUAL MEETING AND THE ELECTIONS.

The extract from the Bye-laws of the Pharmaceutical Society that has appeared for several weeks among the official notices on the first page of the Journal cover, will have conveyed to most of the members a sufficient intimation that all who do not *before* the 1st of May pay the subscription due on the 1st of January last, will, by such default, become incapacitated from taking any part in the ensuing elections of members of Council and local secretaries, or attending the Annual Meeting; indeed, they will thereby cease to be members of the Society. We are induced specially to call attention to this fact, since the meeting of the Council falls this year on the 1st of May, and consequently there will be no opportunity of restoring a lapsed membership before the issue of the voting-papers, which can only be sent to persons whose names are on the Society's books.

We also take the opportunity of alluding to the election of local secretaries, on account of the want of interest and misunderstanding evidently existing in some localities. On several occasions it has devolved upon the Council to appoint local secretaries in the absence of any nomination, while only recently a letter has been received from an old member asking how local secretaries were nominated, and wondering why he himself had never had a turn of office. To any other persons troubled with the same doubts, we would say that in the course of next week a nomination paper will be sent from the office to each Member and Associate in business; and by following the plain directions therein laid down, the recipient may nominate any member of the Society he may please who lives in the district. Considering the important services these gentlemen are frequently called upon to render to the Society, it is to be hoped that each member will do his part in keeping the organization in a state of efficiency.

The next Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, May 1st, when Mr. Greenish will read a paper on "Pharmacy in Austria." The chair will be taken at half-past eight precisely.

A provision has been introduced into the New York Pharmacy Bill, which is still before the legislature, that "junior assistants" or "apprentices in pharmacy" shall not be permitted to prepare physicians' prescriptions until they have become "graduates" or "licentiates" in pharmacy. This would seem to necessitate a very prompt acquirement of the qualification upon ceasing to be an apprentice, and arriving at the dignity of "graduate." Another point that seems to be objectionable is the constitution of the examining board, which, as the Bill stood at the time of our latest advices, was to consist of three graduates of a legally constituted medical college and two graduates of a college of Pharmacy. Assuming that pharmaceutists know their own business best, it is not very clear why there should be a preponderance of medical men amongst their examiners.

Some attention has recently been drawn to the extremely poisonous nature of the sting of *Jatropha urens* by the circulation of a paragraph describing its effects upon the system, experienced by the ex-curator of the Royal Gardens, Kew, who got accidentally stung by it soon after the plant was introduced, about fifty years back. The paragraph in question is essentially correct, but the facts, as given at p. 863, have been obtained from Mr. Smith's own lips.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

April 17th and 19th, 1872.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Haselden, Ince and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR.

Seven candidates presented themselves; of these, *two* failed. The following *five* passed, and were declared duly qualified to be registered as "Pharmaceutical Chemists."

*Hill, William Edward	Leicester.
Wilson, John Herbert	Lee.
Wright, Thomas	Leicester.
Dale, John	Birmingham.
White, William Edwin	Dover.

These names are arranged in order of merit.

MINOR.

Thirty-nine candidates presented themselves; of these, *seventeen* failed. The following *twenty-two* passed, and were declared duly qualified to be registered as "Chemists and Druggists."

	*Cole, Edward Henry	Leeds.
	*Cortis, Arthur Brownhill	Worthing.
	*Appleby, Edward Joseph	Brighton.
	*Evison, William	Louth.
	*Howse, Henry William	London.
	Houghton, Robert William	Bermuda.
	Smart, Charles Frederic	Littlehampton.
	Harrington, Arthur Lewis	Rochford.
	Dixon, John Seth	Tunstall.
	Williams, William Griffith	Abergele.
	Robeson, Charles Brunting	Walworth.
	Bates, William	Stevenage.
	Haworth, Benjamin Henry	Manchester.
	Vince, James	Lancaster.
	Maitland, Alick	London.
	Saunders, Thomas Bealby	Cheltenham.
	Bishop, Charles Edward	Bristol.
	Cottam, William Procter	Lancaster.
Equal.	Blackwell, Frederick William	Birmingham.
	Jones, Mathew Henry	London.
	Maurice, James	Cardigan.
	John, Jabez Arundel	Tenby.

These names are arranged in order of merit.

PRELIMINARY.

The undermentioned Certificates were received in lieu of this examination.

Certificates of the College of Preceptors.

Charlton, John Spark .... Newcastle-on-Tyne.
Wilson, Robert .... Boston.

Certificate of the Society of Apothecaries.

Arrowsmith, George P. ...... London.

Certificate of the University of Cambridge.

Shaw, William .... Shrewsbury.

Certificate of the University of Oxford.

Gutheridge, George Frederick . Falmouth.

The following is the result of the Examination held on the 8th instant:—

ENGLAND AND WALES.

Two hundred and ninety-nine candidates presented themselves for this Examination; of these *one hundred and forty-one* failed. The following *one hundred and fifty-eight* passed, and were duly registered as

APPRENTICES OR STUDENTS.

	Taylor, Edward	Birmingham.
	Jones, William	Beaumaris.
	Shakespeare, Alfred	Leicester.
Equal.	Glyde, Henry Alfred	Bedford.
	Hall, Edward	Norwich.
	M'Knight, John	Hackney.
	Bowness, William	Workington.
	Scoley, Thomas Edward	Boston.
	Brend, Kenneth Benjamin	Swansea.
Equal.	Sanders, Gabriel	Birkenhead.
	Wallas, Thomas Irving	Carlisle.
Equal.	Gilders, George Pollard	St. Leonard's.
	Greenwood, Dennis	Cambridge.
	Jones, James Lewis	Bangor.
	Walton, Daniel	Manchester.
	Richards, Jonah	Cardigan.
	Cardwell, Ernest	Lytham.
	Rigg, John	Preston.
Equal.	Guy, Daniel	Lee Green.
	Hanham, John	Pendleton.
	Howard, George William	Tunbridge Wells.
	Waddington, Charles Edwin	Bath.
	Clayton, William	Howden.
Equal.	Robinson, William Prior	Waterloo.
	Savory, John Field	London.
	Upsall, Edgar Arthur	Holbeach.
	Brown, George German	Dresden.
Equal.	Bates, Edward	Bicester.
	Newitt, Herbert Henry	Bicester.
	Martin, John Wesley	Stratford.
	Parkinson, Frederic William	Peterborough.
	Bibbings, John Henry	Exeter.
Equal.	Elkington, William Alfred	Spalding.
	Haworth, Hezekiah	Blackburn.
	Roberts, Richard Pritchard	Bangor.
	Weedon, Joseph	Crawley.
Equal.	Bradbury, Thomas	Ashton-under-Lyne.
	King, John William	Bolton.
Equal.	Owen, Herbert	Coventry.
	Tracy, James	Kingston-on-Thames.
	Walker, William	Settle.
	Morris, John James	Cardigan.
Equal.	Linney, William Wycliffe	Ashton-under-Lyne.
	Lomax, Alban Edward	Liverpool.
	Stibbs, James	London.
Equal.	Amson, John Henry Occleshaw	Brindley Ford.
	Catford, Obadiah William	Chard.
	Evans, John	London.
	Leigh, Marshall	Middlesbrough.
	Robertson, Robert	Coventry.
	Strickland, Robert Brewster	Manchester.
	Walton, Henry	Manchester.
	Warburton, Walter	Middlesbrough.
	Wingrave, Vitruvius H. W.	Coventry.
	Troughton, Henry	Lancaster.
Equal.	Buswell, Frank	Leicester.
	Cousens, John Stather	Hull.
	Hicks, William King	London.
	Inger, George Edward	Nottingham.
	Salmon, Harold	Oxford.
	Smith, Thomas	South Shields.
	Williams, Walter	Oxford.
	Bridge, William Joseph	Wigan.
	Fresson, Charles Francis	Stevenage.
Equal.	Cobb, Frank	Sheffield.
	Dixon, William	Stratford-on-Avon.
	Watson, Thomas	Wells.
Equal.	Cory, Francis Albert	Newport, I. of W.
	Fawthrop, Thomas	Ryde, I. of W.
	Herbert, William James	Wantage.

*Passed with honours.

Equal.
Briggs, William Henry ...... Wakefield.
Hall, Richard Arthur .... Leigh.
Holliday, John .... Birmingham.
Newlyn, James .... Plymouth.
Peché, John .... Chertsey.
Southern, Charles William.... Donington.

Holt, George Alfred.......... Douglas, I. of M.

Equal.
Machin, William George...... Donington.
Piper, John .... Penzance.
Plumer, John George .... London.
Reeve, George Dunn Reeve .. Portsmouth.

Burden, John Britten .... London.

Equal.
Boultbee, Charles Edward .... Norwich.
Bramley, William............ Uppingham.
Brawn, James Ward .... Birmingham.
Brewerton, Thomas .... Manchester.
Cronkshaw, John .... Manchester.
Dawson, William Hewson .... Horncastle.
Gidney, Stephen William .... Windsor.
Harvey, William .... Walsham-le-Willows.
Jenkins, Alfred George ...... Birmingham.
Law, James .... Blackburn.
Tritton, Charles .... Bristol.
Ware, Emanuel.............. Broad Clyst.

Equal.
Lowe, Arthur................ Lynn.
Smith, William.............. Batley.
Sutton, George Sewell........ Gosport.

Gilbert, Sydney.............. Exeter.

Equal.
Chapman, Walter............ Nottingham.
Eady, Albert Arthur .... Chertsey.
Hartley, Thomas .... Preston.
Hughes, John Williams ...... Manchester.
Lord, John Edward .... Rawtenstall.
Mumford, Richard .... London.
Silverwood, Joseph .... Manchester.
Taylor, Jonathan............ Saltburn-by-the-Sea.
Taylor, William Edward...... Basingstoke.

Howells, William............ Llandovery.

Equal.
Bartle, William Thomas...... Heckmondwike.
Bridges, Ernest Claude ...... Kingsdown.
Mackenzie, Charles Anderson.. Plymouth.
Wilson, William Norman .... Liverpool.

Equal.
Bladon, William George ...... Cheltenham.
Broad, Thomas Benjamin .... Macclesfield.
Davies, John .... London.
Griffiths, David James ...... Cardigan.
Millhouse, Harry How ...... Sleaford.
Pattrick, George .... Long Sutton.
Rowe, Walter .... Leicester.
Spensley, Thomas Brentnall .. Middlesbrough.
Welborn, Otto Francis ...... Eton.

Equal.
Jones, Thomas .... Aberystwith.
Kellett, Richard Edward .... Wigan.

Gooseman, John Brocklesby .. Grimsby.

Equal.
Agger, Joseph Edward ...... King's Lynn.
Catcheside, Matthew Henry .. Hexham.
Harriman, Edwin............ Liverpool.
Northcroft, Arthur .... Plymouth.

Equal.
Barlow, Frederick .... Birmingham.
Fowler, George William.. Hackford next Reepham.
Hill, John Staniforth .... Blackpool.
Rickinson, Francis William .. West Hartlepool.
Sanderson, Edward John...... Stockport.
Sheldon, Arthur E. .... Walsall.

Dimmock, Frederick Augustus London.

Equal.
Hardy, James Hammond .... Filey.
Horril, William Harris ...... Newton Abbott.
Rees, Evan.................. Carmarthen.
Sturdy, Thomas Metcalfe .... Leeds.
Toon, Lionel Edward .... Gosport.
Turner, John................ Bath.

Equal.
Alfieri, Charles .... Stafford.
Frater, Mark................ Rothbury.
Halhead, John Armitstead .... Kirby Lonsdale.
Price, Herbert Ernest .... Ledbury.
Thompson, John Hartley...... Sheffield.

Equal.
Cox, Joseph Bethell.......... Lynn.
Crossley, Newbold .... Bury.
Dee, Walter .... Cheltenham.
Hardy, Frederic Warren...... Wigan.
Harrington, Arthur.......... Needham Market.
Howard, Augustus Frederick.. London.
Kerr, George Jobbing .... Liverpool.
Manock, Edmund............ Preston.
Maxfield, William Ashley .... Darlington.
Owen, Griffith Charles Roose.. Carnarvon.
Sproson, Thomas Frederick .. Wolverhampton.
Walker, Francis .... Liverpool.

The above names are arranged in order of merit.

SCOTLAND.

Forty-eight candidates presented themselves for this Examination; of these *twenty-one* failed. The following *twenty-seven* passed, and were duly registered as above:—

Christie, James .... Oldmeldrum.

Equal.
Hindes, James .... Edinburgh.
Scott, Peter .... Greenock.

Stiell, Gavin, jun. .... Dunfermline.
Forgie, William .... Falkirk.

Equal.
Forrest, John Kerr .... Edinburgh.
Hay, Joseph Pagan .... Dumfries.
Johnstone, Thomas Francis.... Dumfries.
Keith, John .... Glasgow.

Fogg, James .... Dunfermline.

Equal.
Nicholson, John H. .... Moffat.
Smith, Walter J. .... Edinburgh.

Robertson, Charles .... Edinburgh.
Dunlop, Thomas .... Govan.
Hunter, John Carswell ...... Glasgow.

Equal.
Frazer, Samuel M'Call ...... Glasgow.
Meikle, George .... Dunfermline.

Bean, John.................. Edinburgh.

Equal.
Hewetson, William .... Dumfries.
Lee, Alexander Milne .... Strichen.

Webster, James.............. Banff.
Reid, James .... Edinburgh.
Ellis, George .... Banff.
Smith, Patrick Cheyne ...... Oldmeldrum.
Wallace, Robert .... Cupar (Fife).
Murison, John .... Fyvie.
Duffus, George .... Aberdeen.

The above names are arranged in order of merit.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed:—

The Questions for Examination were as follows:—

LATIN.

Translate into English two or more of the following sentences:—

1. Hæc quum pluribus verbis flens a Cæsare peteret, Cæsar ejus dextram prendit; consolatus rogat, finem orandi faciat: tanti ejus apud se gratiam esse ostendit, uti et reipublicæ injuriam et suum dolorem ejus voluntati ac precibus condonet.
2. Eo circiter hominum numero sexdecim millia expedita cum omni equitatu Ariovistus misit, quæ copiæ nostros perterrerent, et munitione prohiberent. Nihilo secius Cæsar, ut ante constituerat, duas acies hostem propulsare, tertiam opus perficere jussit. Munitis castris duas ibi legiones reliquit et partem auxiliorum; quatuor reliquas in castra majora reduxit.
3. Colchicum macera cum acido in vase operto per dies tres; dein exprime, et sepone ut fæces subsidant; denique liquori colato spiritum adjice.
4. Sequenti aurorâ, sumat Olei Ricini quantum satis sit ad alvum solvendum.
5. What is meant by the term Ablative Absolute? and give two illustrations from Cæsar.
6. Write down the prepositions governing an accusative case.
7. Give the Mood, Tense, Person, and Number of each of the following Verbs:—prendit, faciat, prohiberent, macera, adjice, sumat.
8. Explain the difference between Co-ordinative and Sub-ordinative Conjunctions, and furnish examples of each.
9. Name the kind of Verbs which admit of two Accusatives, and give one or more examples.

ARITHMETIC.

10. N. was born in 1769 and died in 1821, how old was he at the time of his decease? and how many years have elapsed between his death and the present time, 1872.
11. How much cloth is sufficient for a cloak which has in it 4 yards of 7 quarters wide of lining, the cloth being but 3 quarters wide?
12. If 3600 have bread for 35 days at 24 oz. each a day, how much a day may be allowed to 4800 men each for 45 days, that the same quantity of bread may serve?
13. Divide $3\frac{1}{6}$ by $9\frac{1}{2}$.
14. What is the value of ·625 of a cwt.?

ENGLISH.

15. Classify the simple pronouns.
16. Into how many classes are Adverbs of Time divided? Give several examples of each.
17. State the general rule for the formation of the Possessive Case, singular and plural, and give examples.
18. Give the Past Tense and complete Participle f the following verbs:—Cost, thrust, beat, build, awake, chide, sew, strive, shear, and cleave.
19. Parse the following:—The Moon threw its silvery light upon the lake.
20. Write from fifteen to twenty-five lines upon *one only* of the following subjects:—
    A. St. Paul's Cathedral.
    B. Easter Holidays.
    C. Boat Races.

NORTH BRITISH BRANCH PHARMACEUTICAL SOCIETY.

The fifth and last Scientific Meeting for the Session was held in 16, Princes Street, on Thursday evening, April 18th; Mr. BAILDON, President, in the chair.

There was a good attendance, and a Paper on "The Natural History and Commerce of Sponges," was read by Mr. JOHN GIBSON, of the Edinburgh Museum of Science and Art.

The paper, which was illustrated by specimens and drawings, and was frequently applauded, is printed at p. 865.

The CHAIRMAN moved a vote of thanks to Mr. Gibson, seconded by Mr. AINSLIE, and cordially carried.

In connection with this subject, there was laid on the table several very valuable specimens of sponges of various kinds adhering to pieces of rock, which had recently been procured from Smyrna, by Messrs. Macfarlane and Co., of Edinburgh, and by them presented to the Museum of the North British Branch. These were viewed with much interest, and frequently referred to during the reading of the paper.

Mr. MACKAY proposed a special vote of thanks to Messrs. Macfarlane for their valuable gift to the Society's Museum, which was seconded by Mr. BAILDON, and carried with applause.

The PRESIDENT then gave his valedictory address:—

In taking a very cursory review of the Session now about to close, I am sure you will agree with me that the North British Branch of the Pharmaceutical Society is under great obligations to those gentlemen who have so kindly given us scientific papers, viz., to Dr. Stevenson Macadam for his interesting lecture on, and experiments with, the colouring agents recently derived from

Coal Tar; to Dr. M'Kendrick for his experiments and lecture on Neurotics; to Mr. James Mackenzie for his paper on Pharmacy in Edinburgh in the Olden Time; to Mr. Wm. Gilmour for his paper on Volumetric Analysis; to Mr. Paton for one on the Museum, its position and requirements; and, lastly, to Mr. John Gibson for the lecture on Sponges we have just listened to with so much interest.

I need not remind you how attractive, as well as instructive, these lectures were; and although the attendance on them was not so numerous as the Council could have wished, still, upon the whole, it has been an improvement upon previous years.

I hope the time is not very far distant when the members of the Pharmaceutical Society will have made so much progress in the scientific and practical knowledge of their profession as to be able to advance the science of pharmacy by original papers and researches, so as to obviate the necessity we at present labour under of drawing so largely upon the kindness of our professional friends who are not directly connected with the Society. I am the more sanguine of this result from the firm stand we are now making against permitting any to enter the portals of our Society who are not able to pass with credit the Preliminary Examination. This is not only an act of kindness to the youth, but is a guarantee that he has received a liberal education. It is also very desirable that, in making his selection of this particular department of science, he should follow the bent of his disposition, and that he should not pursue it from a lower motive only. Should he be fond of his profession, he ought to be able to pass his Minor Examination before the expiry of his apprenticeship, if he avails himself of the advantages open to him in Edinburgh, Glasgow, Aberdeen and other large centres; and I hope the London Council will soon be able to make such arrangements as will facilitate the education of those who are placed at a distance from these centres.

I regret to state that the statistics of the last Session's Examinations show a result less favourable than the Council could have desired. We find that out of 189 candidates, only 124 passed. This shows a large percentage of failures, and indicates but too certainly that there is still much to be accomplished before we can realize the existence of scientific pharmacists throughout the length and breadth of the land.

I have now the pleasure of stating that, after a good deal of consideration, the Council have agreed, with the approval of the London Council, to acquire a lease of very commodious premises in St. Giles Street—a new street made by the directors of the Bank of Scotland, and which is central to both the old and new town. The Council have found it very difficult to obtain premises in all respects eligible. It trusts these may prove to be so. The building is a new one, and it will be November before the Society take possession.

This, you are aware, is a preliminary step in carrying out our friend Mr. Dean's views towards the formation of an extensive museum and library of reference worthy of the North British Branch of the Pharmaceutical Society of Great Britain. These spacious rooms will be open both during the day and evening to all the members of the Society.

I wish to remind both Assistants and Apprentices that the same liberality as formerly is continued by Professor Balfour and Dr. Stevenson Macadam; and I would urge upon all those who have not availed themselves of these advantages, to do so without delay. The best thanks of the Council are due to these gentlemen for the liberal arrangements they have made to facilitate the acquisition of a knowledge of botany and chemistry. It now only remains for me to offer you my sincere thanks for the kindness shown me during this my second tenure of the honourable office of President of the North British Branch of the Pharmaceutical Society.

Mr. YOUNG, in a few remarks, moved a vote of thanks to Mr. Baildon for his efficiency as Chairman, which was seconded by Bailie BLANSHARD, and unanimously carried.

The Secretary then laid on the table the Smithsonian Report, Report of the Proceedings of the American Pharmaceutical Association, and two numbers of the *Pharmacist*, also from America, all of which had been presented to the Society. Having intimated the arrangements for the approaching Session, the meeting adjourned.

ANNUAL MEETING.

The Annual Meeting took place in Elliot's Room, 16, Princes Street, on Friday forenoon, 19th April, at 12 o'clock; Mr. BAILDON, President, in the chair.

At the request of the CHAIRMAN, the SECRETARY read the following

ANNUAL REPORT.

"The Council have again to bring before the Annual Meeting of the North British Branch of the Pharmaceutical Society their usual Annual Report, and in doing so, desire to congratulate the members on the continued success and onward progress of the affairs of the Association.

"The compulsory nature of the legislation embodied in the Pharmacy Bill of 1868 is now commencing to bear the anticipated fruit, and one has only to glance at the number of candidates for the various examinations in London and Edinburgh throughout the past year, to be assured that the statement now made is a correct one. Perhaps special allusion might be made to one branch of the Society's requirements in connection with this subject, viz. the Preliminary Examinations, or the foundation on which the real scientific knowledge of the future chemist and druggist must of necessity be based.

"Referring to these examinations, the Council cannot help expressing regret that there should be so many failures; and they are ready to do this all the more, because they feel that the questions set by the Examiners are neither numerous nor difficult, and such as any youth of ordinary ability and education ought to master with comparative ease. To those young men more advanced than the apprentice, the questions still retain the same character, and ought to form no barrier in the way of entering for the Minor Examination.

"Since April of last year there have been examined in Edinburgh 189 candidates. These comprehend the Preliminary, Modified, Minor and Major. Of this number 124 passed and 65 failed. The percentage of failures continues to be so large that the Council hope considerable improvement will be made in this department ere the Report for another year is issued.

"Change in the accommodation necessary for carrying on the operations of the Society in Edinburgh, including Examinations, Museum, Library, Meetings, etc., has produced not a little discomfort and awkwardness. This, however, the Council are pleased to intimate is nearly at an end, as they have now the prospect before them of a more steady arrangement.

"The Society in London is about to lease the new rooms in St. Giles Street, in process of erection, near the Bank of Scotland, being not only a central position for the old and new town of Edinburgh, but in close proximity to the general railway terminus; occupation will, it is hoped, be obtained in good time to commence the next winter session of 1872–73.

"The same opportunities as to the teaching of Theoretical and Practical Chemistry continue to exist, while the approaching summer course of Botany in the Royal Botanic Gardens will be open as before to all students in Pharmacy.

"The Council take this opportunity of expressing their thanks to Dr. S. Macadam and to Professor Balfour for their kindness in admitting pupils studying Chemistry and Botany on such advantageous terms to their classes.

Of the opportunities thus afforded, it may be mentioned that during last session 15 took advantage by attending Chemistry, and 12 by attending Botany, or, in all, 27. The Council will be pleased to find these numbers very much increased during the next session.

"The Council feel there is still a want of sufficient energy in connection with the Evening Scientific Meetings; and, while they heartily thank those gentlemen who have contributed during the past winter to render them both pleasing and instructive, they do hope that when fairly in possession of the Society's own rooms, more ready and extended assistance may be given to increase the number and interest of these meetings.

"One great advantage among others will accrue when possession of the rooms is obtained, namely, that both library and museum will be made more available for those who are entitled to use them. And this (of course, under certain restrictions) at any time during the day or evening. Every effort will be made by the Council to accommodate those who may be disposed to take advantage of the privileges which will then be offered.

"The Council have taken all the means in their power to make known the date and place of their Annual Meeting, and will be glad to find that members and associates in business, in and around Edinburgh, as well as those at a distance, may find it convenient to attend and take part in the proceedings.

"Various proposals have been and are still agitating the minds of many, in and outside the Society, in regard to monetary grants to be provided for Provincial Education.

"The Council feel that the importance of this question cannot be over estimated, nor can they deny that the difficulties in the way of coming to a fair and equitable conclusion of the matter are numerous, and not easy to overcome. Still, they have every confidence in believing that the London Council, who hold the reins, will give this important subject due consideration, and that they will yet be able to prepare and launch a plan, which, while it will effect the object in view, will also prove satisfactory to all who take an anxious part in desiring the education of the young pharmacist.

"It has been usual to submit to the Annual Meeting a statement of accounts for the preceding year. This has, however, already been done up to 31st December, 1871; and, after being properly vouched, sent to London, in order that it might pass through the Finance Committee there, and afterwards be presented at the Council Board.

"In closing the Report, and looking forward to increased space and additional cases for the Society's Museum, the Council will be pleased to receive presentations from any one disposed to contribute. Proposed specimens may be intimated to the Curator of the Museum, or to the Secretary. Show cases, bottles, or jars will be willingly supplied for any articles requiring them."

Mr. Anderson, of Musselburgh, Mr. Young, Mr. D. R. Brown, and several other gentlemen made some remarks on the clause in the Report wherein reference was made to anticipated grants in connection with education, the indications of which were a strong desire that very soon the London Council would see their way to carry out the feeling now so largely and almost universally held on this subject, and hoped that without much further delay a portion of the funds of the Society would be so judiciously distributed as to assist the cause of education in certain districts, where, at present, sufficient facilities do not exist for educating apprentices and others.

Thereafter the adoption of the Report was moved by Mr. Baildon, chairman, seconded by Mr. Fairlie, of Glasgow, and carried unanimously.

Mr. Anderson, of Musselburgh, then proposed Mr. H. C. Baildon as president, and Mr. Wm. Gilmour as vice-president for 1872-73, which was seconded by Mr. Frazer, of Glasgow, and carried unanimously.

Both gentlemen made suitable replies.

The Meeting then proceeded to elect the Council for the next year, and after ballot had been taken the following were declared duly elected.

Messrs. the President and Vice-President of the North British Branch, and W. Ainslie, D. R. Brown, G. Blanshard, J. Gardner, A. Noble, R. Raimes, J. R. Young, Fairgrieve, A. Napier, Heron, James Aitken, and Kinninmont, Frazer, Davison and Fairlie, of Glasgow, with the President and Vice-President of the Society in London *ex officio.*

The following gentlemen were then nominated as Examiners for 1872-73, viz.:—

Messrs. Buchanan, Ainslie, Aitken, Kemp, Gilmour, Young, Noble, and Kinninmont, of Glasgow.

Library and Museum Committee: Messrs. Aitken, Brown and Mackay.

Mr. Brown to be Convener.

Mr. Paton was re-appointed Curator of Museum.

Mr. Baildon proposed that Mr. Mackay be requested to continue to act as Honorary Secretary to the North British Branch, and in doing so expressed his sense of the valuable services which Mr. Mackay had for so many years rendered to the Society. He alluded to the amount of labour which Mr. Mackay had had during the past year in connection with the arrangements for the new premises in which the Society are about to enter, and to the satisfactory result attained, and trusted that Mr. Mackay may be long spared so as to see the success of his arduous services in connection with the Society.

Mr. Mackay replied.

In connection with the retirement of Mr. Brown as one of the Examiners in Edinburgh, Mr. Kemp begged to propose a special vote of thanks to that gentleman for his able and great services connected with the office, which he had so long efficiently filled. Mr. Kemp expressed much regret that the step now taken by Mr. Brown should have been occasioned chiefly on account of his failing health, but could not resist taking this opportunity of remarking how much they had been indebted to Mr. Brown for the important aid which he had given to the Society. Mr. Brown's position and scientific attainments were of no ordinary description, and he knew of no one whose presence would be more missed at the Examining Board than Mr. Brown.

Mr. Baildon seconded this, and conveyed the thanks of the Meeting and the Society to Mr. Brown, who made a very feeling reply, referring to the great pleasure which he had always had while giving his assistance to carry on the affairs of the Society.

Before separating Mr. Mackay called for a hearty and cordial vote of thanks to Mr. Baildon, who had for a second time acquitted himself so ably and so well in guiding the affairs of the North British Branch, and stated that he felt all the members were under a deep debt of gratitude to Mr. Baildon for the more than efficient manner in which he had conducted business as President.

Mr. Baildon replied, and the Meeting adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Eleventh General Meeting was held at the Royal Institution, April 11th. The President in the chair.

Mr. W. Morris, chemist, West Derby road, was elected a member.

The following donations were announced:—A set of MSS. Prescriptions from Thomas Hyde Hills, Esq., current numbers of the Pharmaceutical Journal from the Society, and the "Proceedings of the American Pharmaceutical Association, Sept., 1871," from the Association.

The President (Mr. E. Davies, F.C.S.), then read a paper on "Artificial Alizarine," of which the following is an abstract:—

Modern chemistry is characterized by the special importance given to synthesis. Since urea was formed artificially efforts have constantly been made to imitate the work of nature, and build up by chemical art the products found in vegetables and plants. A large measure of success has attended these investigations, and not only are we year by year getting more mastery over this, at one time thought hopeless field of work, but in the examination of the substance to be imitated we get more knowledge of it. Particularly was this the case with alizarine; misled by inaccurate analysis experimenters were working in the wrong direction, until Messrs. Graebe and Liebermann began by getting a clear insight into the constitution of alizarine, and then knowing what had to be done, they, by a brilliant application of theory, obtained what may be considered to be the greatest triumph which chemistry can boast for many years past. Alizarine, the colouring principle of madder, has been the subject of many investigations, but from the difficulty of getting it pure the analyses were not concordant, and the formulæ proposed for its composition were not only varied, but, as it turns out, all wrong. Schunck believed it to be $C_{14}H_{10}O_4$, which is only in error by having 2 H too many. Strecker believed it to be $C_{10}H_6O_3$.

Graebe and Liebermann treated pure natural alizarine with powdered zinc. This reducing agent produced a hydrocarbon $C_{14}H_{10}$, which was proved to be identical with anthracene—a solid body contained in the best products of the distillation of coal tar. Having thus got anthracene from alizarine, the next step was to make alizarine from anthracene. They proved by their experiment, above-mentioned, that alizarine had not the composition assigned to it. It was almost certain that it was really $C_{14}H_8O_4$, and on this assumption, which has turned out to be correct, they worked. In 1861, Professor Anderson, of Glasgow University, had studied the anthracene compounds, and found that by the long-continued action of dilute HNO_3, specific gravity 1·2, a crystalline body was formed, to which he gave the name of oxanthracene $C_{14}H_8O_2$. This is now called anthraquinone for the following reason: from quinic acid contained in Peruvian bark a substance, quinone, $C_6H_4O_2$, is obtained. This is derived from benzol, C_6H_6 by replacement of 2H by 2O, one O partly saturated by the other O. Quinonic acid, $C_6H_4O_4$, is obtained by action of of potash on quinone. In like manner, we have $C_{14}H_{10}$ (anthracene), and $C_{14}H_8O_2$ (anthraquinone), and Graebe and Liebermann assumed that alizarine was the corresponding quinonic acid. Alizarine is an acid, and may be called alizaric or anthraquinonic acid. The first method adopted was to convert anthraquinone, $C_{14}H_8O_2$, into bibromanthraquinone by the action of Br. This gave $C_{14}H_6Br_2O_2$, and by heating with concentrated solution of KHO the Br was replaced by KO, forming $C_{14}H_6O_2(KO)_2$. This was decomposed by HCl giving $C_{14}H_6O_2(HO)_2$, or alizarine.

This method was, however, too expensive for practical purposes, owing to the high price of bromine, and the original inventors, together with Mr. Perkin, the inventor of mauve, worked in another direction. The anthraquinone was converted by the action of H_2SO_4 into disulphoanthraquinonic acid $C_{14}H_6O_2\left\{\begin{matrix}HSO_3\\HSO_3\end{matrix}\right.$ Potash then converted this into alizarine. The alizarine thus produced is in all respects similar to natural alizarine. The crystals are red needles in both cases, both give the same colour with KHO, and dye mordanted fabrics of the same colours, and equally fast. Cupric acetate gives the same purple colouration to the alcoholic solution; the absorption-bands in each are the same.

Anthracene is found to the extent of half per cent in coal tar, but it appears probable that a much larger amount may be obtained by the regulation of the heat in making gas. The importance of this discovery is seen at once on referring to some statistics of Dr. Roscoe in a recent lecture, where he shows that the annual production of madder is about 47,500 tons, worth £45 per ton, equal to £2,150,000. Of this we take about half, so that about £1,000,000 annually represents the sum which we pay to foreign countries for a substance which we may in future prepare at home. It is used at present for Turkey red dye, and some other styles of madder dyeing.

A vote of thanks to Mr. Davies for his interesting paper closed the proceedings.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

At the rooms of the above Society, Mr. R. H. Rowell, Chemist, of Houghton-le-Spring, delivered a lecture on "Chemical Affinity."

There was a large attendance of members present, and the lecture, which was illustrated by a variety of experiments, was highly appreciated by the audience.

At its close some discussion arose, the chief speakers being Mr. B. S. Proctor and Mr. Simpson; after which a hearty vote of thanks was proposed by Mr. Shaw, seconded by Mr. Marshall, and carried unanimously.

Mr. Rowell responded in a few suitable remarks.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, April 18th. The President, Dr. Frankland, F.R.S., who occupied the chair, announced the presence of Professor Himly, of Kiel, and of Professor Eschenburg as visitors.

After the usual business of the Society, the Secretary read two papers by Mr. E. A. Letts: "On Benzyl Isocyanate and Cyanurate," and "On a Compound of Sodium and Glycerine."

Professor Himly, who spoke in German, then gave an account of a new method of determining the carbonic acid in sea water, and of an apparatus for collecting the water at great depths, which could be immersed to the required distance below the surface, and there closed by means of stopcocks. These are turned by powerful springs, released at the proper moment by an electro-magnet.

There was also a short note by Dr. E. T. Thorpe, "On the Action of Phosphorus Pentasulphide on Tetrachloride of Carbon;" and another, "On the Degree of Solubility of Silver Chloride in Strong Nitric Acid," by the same author.

Dr. Hofmann, F.R.S., then gave a brief account of the new phosphorus basis which he had recently obtained by the action of alcoholic iodides on iodide of phosphonium in the presence of zinc oxide; and illustrated his remarks by several striking experiments.

The meeting was then adjourned until Thursday, 2nd May, when Mr. E. Riley will deliver a lecture on "The Manufacture of Iron and Steel."

PHILADELPHIA COLLEGE OF PHARMACY.

At the Pharmaceutical Meeting of this College on March 19th, a paper was read on the "Strength of the Officinal Tincture of Opium," by Mr. A. Shryock; and one on the "Amount of Moisture contained in Dried Drugs,' by Mr. G. W. Kennedy.

Professor Parrish presented, on behalf of Messrs. Cramer and Small, a specimen of fixed oil, obtained from 15 lb. of nux vomica, in the process for making the alcoholic extract. The weight of the oil was 2½ oz.; that of the extract after its separation, 18 oz. The oil was of a dark brown colour and very bitter to the taste.

Professor MAISCH remarked that he had not separated the oil in making this extract on the large scale, on account of its bitterness; but that by concentrating the tincture to a syrupy consistence, mixing a little water, and evaporating, the oil may be almost completely diffused throughout the mass.

Professor PARRISH prepared, in the presence of the meeting, a vial of emulsion of oil of turpentine by the process of Mr. J. W. Forbes;* and said that after many years' experience with this class of extemporaneous preparations he had found this plan to be a real improvement, both in regard to convenience and the perfection of the resulting preparation. He also showed emulsionized ether and chloroform made by the same process. In the latter, the chloroform, in consequence of its greater specific gravity, subsided in the vial, but was completely diffused by shaking.

Professor MAISCH exhibited some oil of *Eucalyptus globulus*, said to be used for the adulteration of other oils, it having a delicate odour, easily covered by bergamot and more powerful perfumes. The leaves yield six per cent. of the oil which is met with in commerce at from $1.50 to $2.00 per lb. Also a specimen of gurjim balsam, or wood oil, which he said is used in Germany for the same purposes as copaiba. It is obtained from several species of *Dipterocarpus*, indigenous to the East Indies, resembles copaiba in odour, though dark and opaque, and has a bitter taste. At 230° to 260° it becomes thick and almost gelatinous; above that temperature it is limpid.

At the Annual Meeting, which was held on the 25th March, the following officers were elected for the ensuing year:—*President*, Dillwyn Parrish; *Vice-Presidents*, W. Procter, jun., and Robert Shoemaker; *Treasurer*, Samuel S. Bunting; *Recording Secretary*, Charles Bullock.

CHICAGO COLLEGE OF PHARMACY.

The Annual Meeting of this College was held on Wednesday, March 6th, Mr. E. H. SARGENT, the President, in the chair.

After the reports had been read the PRESIDENT proceeded to deliver his address. The chief topic dealt with was the great calamity which, since the preceding anniversary, had overtaken their city. He expressed an opinion that while the conflagration, in its extent, the vastness of the injury, both public and private it caused, and the terrible suffering it entailed, was without a parallel in history, the world had hitherto seen no such exhibition of the goodness existing in the human heart as was manifest in the wonderful universal sympathy and benevolence to which it gave rise. In this overflowing charity the College and its members were not forgotten, and the whole-hearted efforts of their friends were the first glimmerings of light in their discouragement and gloom, giving them hope and energy to overcome the disaster. Immediately after the fire the druggists of New York placed a large fund in the hands of one of their number for the relief of those connected with the business who had suffered, and the druggists of San Francisco had sent a liberal contribution for the relief of any distressed member of the College. Of a different character, but quite as important in the reorganization of the College, was the benefaction of the Philadelphia College of Pharmacy, where books and specimens were being collected for the library and cabinet. From over the broad Atlantic, too, distant but not less generous friends had arranged for a most comprehensive endowment, including the refurnishing of the library and museum with a collection of books and specimens in many respects not inferior, and in some departments more complete than that they had lost. It was especially worthy of notice that the list of donors, embracing the names of those most eminent in English pharmacy, also contained those of a large number of students and apprentices, showing how deeply the sympathies of all were stirred by the misfortune. This notable feature of the gift would endear it to each one of them a thousandfold, and cause them to honour the young men and the system of instruction which led to such noble results. It must not be forgotten that these gifts would be a trust confided to their care to help them in the education and training of their clerks and apprentices to become qualified pharmacists, and that they would best show their appreciation of them by using all their energies to make the College more useful to students than it had ever before been.

At the conclusion of the President's address, Professor BARTLETT submitted the following resolutions, which were, on motion, adopted.

"Whereas, we have learned of the generous purpose of individuals, firms, and associations, in this country and Europe, toward this College, in making to us contributions of books, apparatus, etc., with the intention of re-establishing it among the institutions for the advancement of pharmaceutic science and art;

"Resolved, That we recognize on the part of the donors of these offerings, a kindly human sympathy; a highly complimentary appreciation of the works of this College, and a pleasing evidence of that common interest which binds together the cultivators of science in all countries."

"Resolved, That these contributions to the advancement of pharmaceutical science are received with a full sense of the responsibility which rests upon us, the recipients; and we hereby pledge ourselves to use our utmost endeavours to make this College worthy of the generosity which has been so kindly extended to it by its distant friends.

"Resolved, That we tender to each and every contributor the heart-felt thanks of each member of this College.

"Resolved, That the names of the donors be procured by the Secretary of the College, and preserved in a suitable form in the archives of the institution."

The following officers of the College for the ensuing year were then elected:—*President*, George Buck; *Vice-Presidents*, T. H. Patterson and J. W. Mill; *Secretary*, G. M. Hambright; *Treasurer*, A. C. Vanderburgh; *Corresponding Secretary*, Albert E. Ebert.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.........*Medical Society*, at 8 P.M.
April 29. *Society of Arts*, at 8 P.M.—"Silicates, Silicides, Glass and Glass Painting." By Professor Barff (Cantor Lecture).
London Institution, at 4 P.M.—"Elementary Botany." By Professor Bentley.

TUESDAY ......*Royal Institution*, at 3 P.M.—"Development of Belief and Custom." By Mr. E. B. Tylor.
April 30.

WEDNESDAY ...*Pharmaceutical Society of Great Britain*, at 8.30 P.M.—"Pharmacy in Austria." By Mr. T. Greenish.
May 1. *Society of Arts*, at 8 P.M.
Royal Institution, at 2 P.M. — Annual Meeting.

THURSDAY......*Royal Society*, at 9 P.M.
May 2. *Royal Institution*, at 3 P.M.—"Heat and Light." By Dr. Tyndall.
Chemical Society, at 8 P.M. "The Manufacture of Iron and Steel." By Mr. E. Riley.
Linnean Society, at 8 P.M.

FRIDAY ....*Royal Institution*, at 9 P.M.

SATURDAY ......*Royal Institution*, at 3 P.M.—"The Star Depths." By Mr. R. A. Proctor.
May 4.

* See the paper describing this process, *ante* p. 747.

UNG. HYDRARG. OXIDI RUBRUM AND UNG. HYDRARG. NITRATIS.—Mr. C. C. Fredigke states, in the *Pharmacist* for February, that ung. hydrarg. oxidi rubrum may be preserved for an indefinite length of time by keeping it beneath a layer of glycerine half an inch thick. He has found ointment so treated to have just as fine an orange chrome colour after being kept eighteen months as when first made. He says also that the ung. hydrarg. nitratis may be prevented from becoming hard by incorporating with it, while warm, one-fourth of its weight of glycerine in small quantities at a time, rubbing after each addition until all the glycerine is extinguished. Ointment so prepared does not lose its fine citrine colour till after a year or more.

PREPARATION OF ABSOLUTE ALCOHOL.—Erlenmeyer (Annalen der Chemie und Pharmacie) proposes a slight modification of Mendelejeff's method of preparing absolute alcohol by distilling together alcohol having a specific gravity not higher than 0·792 with pieces of quicklime projecting above the surface, which only gives the middle portion of the distillate anhydrous. If, however, the alcohol and lime be heated by a water-bath for half an hour in a still connected with a return cooler, and then the cooler reversed and the alcohol distilled, Erlenmeyer states that the entire distillate is obtained in an anhydrous condition. If the alcohol contain more than five per cent. of water it must be submitted to the same treatment two or three times, but the lime should not at first project above the alcohol, and should be present in smaller proportion, as the rapid hydration endangers the still.

MISTURA CRETÆ.—The following is the formula according to which the specimen of mistura cretæ was prepared that was exhibited at a recent meeting of the Philadelphia College of Pharmacy (see *ante*, p. 775), in perfect condition after having been kept ten months:—

℞ Cretæ Præp. ℥ss
Glycerini ℥ss
Pulv. Acaciæ ʒij
Ol. Cinnamomi gtt. viij
Aquæ Dist. ℥viij

Mix thoroughly.

BROMIDE OF CALCIUM.—Mr. James R. Mercein, of Jersey City, communicates to the *American Journal of Pharmacy* the following method for the preparation of bromide of calcium:—A strong solution of hydrobromic acid is produced by passing sulphuretted hydrogen slowly into a half-gallon specie jar containing five ounces of bromine and two and a half pints of water, through a delivery tube touching the surface of the bromine, until all the bromine is taken up; the resulting liquid is filtered from the copious deposit of sulphur, gently heated in a capsule and again filtered. In order to free it from any possible impurity, it is distilled at a sand-bath heat until four-fifths has passed over. To the hydrobromic acid so obtained, precipitated carbonate of lime is added in slight excess; the solution evaporated by a water-bath to a syrupy consistence, removed from the bath and stirred till cool. The result is stated to be six ounces of bromide of calcium in fine granular powder, possessing every characteristic of the salt, and freely soluble in twice its weight of water, leaving a mere trace of residuum on the filter. The cost of preparation is one-fifth the market price of the commercial article, which frequently contains some uncombined lime.

EDIBLE FUNGI.—Meeting a friend some days ago, I found him bound upon an excursion to a certain pasture not far from the city, in search of what he called "Jew's lugs," with a dish of which, prepared into a kind of soup, he is in the habit of regaling himself once, at least, in the season in which they are to be found,—the early spring. I would be much obliged if you could inform me in your correspondence column, to what species they belong. The only thing I can find in any of my books under the name of Jew's ears, is *Exidia auricula judæ*, Linn., but they grow upon trees. These, however, grow in pastures, and only in a *few* places, at least hereabouts. They grow close to the ground with no stem visible. The specimens enclosed are somewhat shrunken, having been kept a few days.—W. M.

[*** The specimens sent by our correspondent were submitted to Mr. M. C. Cooke for examination, who writes as follows respecting them:—"The fungus sent to me is *Peziza venosa*. It is called Jew's ears in some parts of the country, and has long enjoyed the reputation of being edible, as well as *Peziza acetabulum*. Its odour, when stale, is more like that of the mushroom than any other *Peziza* with which I am acquainted. In the *Gardeners' Chronicle*, some time since, I think there was a letter published vindicating its esculent properties under the name of "Jew's ears," but I cite this from memory, and am unable to give more precise reference."—ED. PH. J.]

ADULTERATION OF OIL OF NEROLI.—Schramm states (Dingl. Pol. Journ. cci. 375) that copaiba oil may be detected in oil of Neroli, if present, by mixing a few drops with spirit and burning the mixture on cotton wool. When the spirit has burnt off, the smell of the copaiba oil can be distinguished.—*Journal of the Chemical Society.*

DANDRIFF.—The following remedy for this affection is taken from the *New York Druggists' Circular*:—

Carbolic Acid, ʒss
Oil of Bergamot, ʒj
Glycerine, ℥ij.

In addition, the frequent use of warm water and soap is recommended. See also *ante*, p. 637.

Hospital Dispensing.

Sir,—My attention has been drawn to your leading article of this day's date on Hospital Dispensing.

I regret that you were not made acquainted with the real facts of the case, as you would then have arrived at a very different conclusion with reference to our dispensing department. They are as follows:—

One of our porters obtained from one of our qualified dispensers a supply of cough linctus, as if for himself, he having previously derived personal benefit from its use. He was allowed to have the medicine—the bottle being duly labelled—just as a servant or apprentice in a druggist's shop would be permitted to have medicine for his own use. Unfortunately, his object, good in itself, was productive of evil results. He gave it to a friend, by whom it was administered to his own child. The ultimate consequence was not therefore traceable to the hospital, but to the mistaken kindness of the porter and the misplaced faith of the parent of the child.

If you were to pay a visit to this hospital, I should be content to abide by your verdict as to our dispensing arrangements, which, looking to the extent of our out-patient department, are, I believe, as complete as any in London.

Wm. J. Nixon,
House Governor and Secretary.

London Hospital, Whitechapel Road, E.
April 20th, 1872.

[*** The hospital seems to have been inadequately represented at the inquest, when the facts detailed were accurately as described in our article, and led to a decided expression of opinion from the coroner and jury in condemnation of the arrangements so described. We are glad to learn from Mr. Nixon that the hospital has a better case than was then presented. The suggestion, that we should visit and report upon the dispensing arrangements, accords with an opinion which we have for some time entertained that such an inquiry, systematically carried out at all the hospitals, would be for the public good. We should not be unwilling to undertake it, if proper facilities were afforded.—Ed. Ph. J.]

Sir,—The following paragraph (which I fear has escaped your notice) certainly deserves insertion in the columns of your Journal, in order that it may not be lost to the pharmaceutical world, as illustrating the liberality of the Committee of the Dover Hospital:—

"According to the *Kentish Express*, the Committee of the Dover Hospital have appointed a dispenser at a salary of 5*s.* per week! We pity the patients."—*Medical Times and Gazette, April 13th*, 1872.

A hospital dispenser (from the responsible office which he holds) should be an educated and experienced pharmaceutist, one who has expended time and money in qualifying himself for the proper fulfilment of his important duties. To obtain such a man fair and even liberal remuneration should be given. Cases of accidental poisoning in hospitals (such as that reported in your last week's Journal) would then be of rare occurrence.

The Committee of the Dover Hospital can set but little value upon the lives of their patients when they pay their dispenser the paltry salary of £13 per annum.

F. J. Barrett.

Wolverhampton, April 22nd, 1872.

The Election of Council.

Sir,—In anticipation of the impending election, I am anxious to ask each voter to consider the claims of the Midland district, of which Birmingham is the great industrial centre, to a representative. It is at present unrepresented.

The Council of the Midland Counties Chemists' Association, at a recent meeting, unanimously resolved, on consideration of the subject, that Mr. John Churchill, of New Street, Birmingham, should be proposed as a suitable representative. He has accordingly been nominated, and appears in the published list of candidates who have accepted their nomination.

A kind but unknown friend has also, I find, nominated me; and though I have been solicited by several of my friends to stand, I have been compelled by various considerations to decline doing so.

May I, on this account, advance the request, and ask, apart from the personal claims of Mr. Churchill, and of the Midland district to a representative, that those who might have given their votes to me, had I elected to stand, would bestow them upon him. I am sure he will not disappoint the confidence of the constituency.

George Dymond,
President of the Midland Counties Chemists' Association.

Birmingham, April 23rd, 1872.

Co-operative Dispensing.

Sir,—I hope the discussion now being carried on as to the rights and the wrongs of apprentices may lead to a result of practical and permanent benefit to each party interested; at the same time it must be borne in mind that no hard-and-fast line can be laid down,—the time allowed and the facilities offered for study must necessarily vary, and it would be gross impertinence on the part of a London chemist to dictate to a provincial, and *vice versâ*. Let it be granted that proper facilities should be allowed, the details must depend upon the nature and requirements of the special business. But while we are trying to help the apprentice, cannot we do something to help ourselves? By so doing we should greatly assist him and make the business (we cannot yet call it a profession) worth the trouble and expense this high standard of education necessitates. No one living in London can fail to recognize the fact that the co-operative system is seriously affecting the retail part of a chemist's business, and unless means are taken to secure the dispensing of medicines to the duly qualified chemist, it will not answer the purpose of any one to enter the trade.

I think that agitation in this direction would be a perfectly fair and legitimate one for chemists, as a body; in the course of time it must succeed, and the sooner it is set about the better. Is it fair or reasonable to insist upon young men going through a course of study involving considerable expense, with the magnificent prospect of standing behind a counter and acting as agents for the sale of goods bringing no more profit than is obtained by his neighbour the grocer, who has at least the advantage of making ten times the return? Let the cry of the trade be "Agitate, agitate, agitate," but also "Educate, educate, educate." I believe it is to be done, and would meet with the support of the medical profession.

Henry Lawrence.

Kensington, W., April 20th, 1872.

Provincial Pharmaceutical Education.

Sir,—In reply to the remarks of J. P. (Sheffield), I would state that at the outset he admits a difficulty in maintaining a school in the country—the difficulty of finding qualified teachers, who have the leisure to teach—the men who are wished for having to attend to their own business.

J. P. says, "Either the lectures, etc., must be gratuitous or remunerated." Why should they be gratuitous? Does the student not have to pay for his instruction before he is bound apprentice? And why should he get teaching gratuitously afterwards? If the Pharmaceutical Society be induced to give instruction gratuitously, it would then be like a School Board, which has the power of taxing in order to provide instruction for those who cannot afford to pay for it. Of course, the student must pay for learning "from highly gifted gentlemen."

Again, J. P. states, "The expenses, incidental or otherwise, connected with attendance in London are such as to form a barrier to the majority of those who are apprenticed in the country." Form a barrier! Why should they? Ought any one to expect to acquire first-class instruction for nothing? Is any one authorized to enter a business without having the funds necessary to carry him through? And should the coffers of the Society, which J. P. says are so full—but which I doubt—be opened to assist this needy class?

"The school at Bloomsbury Square may, and does, answer for the metropolis, but is it suitable to the provinces? We provinces—answer, No!" I should like to know of whom this "we" consists. In the opinion of many well qualified to judge, the number of country schools (?) is sufficient, and in some cases more than sufficient, for all intents and purposes. Does J. P. desire to have a school in each provincial town? If so, has he ever thought of the expense of supporting each school? I dare venture to say that £200 a year could very soon be expended upon *one* country school if it were conducted properly. What, for instance, would a respectable, highly qualified teacher of chemistry (a great desideratum) require, say, for fifty demonstrations in practical chemistry, and fifty lectures=100 lessons? Is he not entitled to £100 for this? And how would this amount of money be raised? Could the local association contribute £50, and would the fees from the members in that country town amount to so much as to make up the £100—these fees of the members going at present into the Society's coffers according to J. P.'s views.

But only one subject is thus provided for. A teacher of chemistry might be got to go through a course of instruction for £30 or £40; but anyone who knows what sound chemistry is would immediately conclude that to do the job for this price, it would be done in a slip-shod manner; for £10 would be required for the demonstrations alone.

Then come difficulties connected with pharmacy, botany, and materia medica, subjects equally important with chemistry, but which I cannot now dwell upon. J. P. mentions a gentleman giving his services gratuitously. A competent person giving his labours for nothing is what we very rarely see. All those whose learning has cost much are not very willing to impart it for nothing. Some persons may be found to do so; but do they not do it for publicity, popularity, or applause, of which they soon become tired, finding it a losing game? Therefore an association should not rely upon voluntary teachers. It strikes me that the proper teacher, who would of course show his qualifications or diplomas, would demand, and justly so, a suitable recompense for his services. How many of our better chemists take apprentices for nothing? How many are willing to diffuse their learning gratuitously? Are they not authorized to expect a good return for capital invested in acquiring their knowledge? "Many associations are beginning to suffer." Yes, and in my opinion they always will suffer. I could say something on the impossibility of maintaining a school in the country; but this subject I must defer for the present.

Lastly, J. P. says, "Is it not the duty of the parent society to grant £300 a year to the provincial associations?" No! because doing so would be unfair, undesirable, impracticable, impossible. Again, why no? If the £300 were spent upon one association alone, it would not be a halfpenny more than would be required.

Let us look beyond our own body and profit by the experience of others. Has the Royal Veterinary College any country schools? Why? How many country schools has the Royal College of Surgeons? And why is it proposed to close them? How many other learned societies have not country schools, and why?

A Country Major Associate.

Tinct. Ferri Perchloridi.

Sir,—With reference to the note on Tinct. Ferri Perchlor. B. P., by Mr. Wilson, in a recent Journal, I would suggest the following as a still more simple and economical formula than the one he there gives:—

Liq. Ferri Perchlor. Fort. ℥v.
Aq. Destillat. ℥v.
Sp. Vini Rect. ℥x.

This I have been using for some time with most satisfactory results, and since the Spirit. Vini Rect. is not only a useless, but expensive ingredient, the above formula might, I think, be conscientiously adopted, the addition of water being preferable to glycerine, as it would be keeping nearer to the official form.

G. C. Druce.

Small Debts Bill.

Sir,—I am surprised no one has noticed your judicious reference to Mr. Bass's preposterous attempt at legislation on small debts. Every tradesman I have mentioned it to seems ignorant of the matter, and almost the universal remark is, "Surely a Bill attempting such absurd injustice will never pass;" but we see a man of business like Mr. Bass introduces it, and if no opposition is expressed, it may slip through the House. Surely every chemist should write to his member about it, and urge his neighbour tradesman to do the same. It would be worth while for each one also to send a post-card to Mr. Bass himself. This would surely prevent his ever attempting such a measure of confiscation again. No doubt his intention is to prevent the mischief caused by the "tally system," by which pedlars push their goods on foolish customers; but to interfere with all legitimate retail trade to do this, is as wise and as necessary as it would be for the police to handcuff every man and woman in a fair to prevent pocket-picking.

W. Symons.

Barnstaple, April 22nd, 1872.

A. P. S.—We consider that the means of preparation mentioned ought to be sufficient.

"*A Student.*"—Redwood's 'Practical Pharmacy.'

"*Inquirer*" (London).—You are recommended to use an equivalent quantity of chemically *dry* sulphate of zinc.

"*Inquirer*" (Aberdeen).—You would have to conform to the law prevailing in the particular State.

C. Andrews.—See an answer to a similar question at p. 660 of the present volume.

H. James.—A paper read by Mr. Abraham before the Liverpool Association, printed at p. 711.

X. Y. Z.—'How Crops Grow,' published by Macmillan and Co.

"*An Assistant.*"—(1.) No. (2.) No. (3.) It should be labelled, "Shake the bottle."

H. Edmonds.—We should think the Collodium Flexile, B.P. is intended.

"*A Student.*"—(1.) Yes, within a fraction. (2.) To prevent loss of phosphate of lime: see Dr. Tilden's 'Chapters for Students,' Vol. I. p. 844.

J. Horncastle.—We have applied to the author of the paper, who informs us that a reference to the original formula shows that the quantity should be one grain.

C. M.—(1.) One to three fluid drachms. (2.) Yes.

H. Rayson.—Vermin killers of any kind can only be sold by registered chemists and druggists. It is not necessary to label phosphorus paste, but we think it would be expedient to do so.

S. N. Holgate.—It is a point on which there is a difference of opinion whether vermin killers containing strychnine or arsenic should not be dealt with as directed for poisons in the first part of Schedule A.

"*Ranunculus.*"—Instructions are given in most elementary works on botany.

"*A* (*Very*) *Modified Man.*"—The subject is one upon which we cannot express an opinion; it is rather a matter for mutual arrangement between the parties concerned.

J. Smith.—Several memoirs by M. Pasteur on the subject have been read before the French Academy, and are printed in the 'Comptes Rendus.'

"*An Assistant.*"—The Pharmacy Act does not prescribe any restriction. With regard to the second part of the question, our correspondent's own sense of right and wrong should enable him to answer it as well as we could.

W. R. Richards.—(1 and 2.) We are not aware of any danger, or (3) any fatal accident that has resulted from its use. (4.) This question is upon a medical subject. (5.) It would depend upon the nature of the impurity.

"*Dominus Salus Mea*" and *W. H. Barr Hamilton.*—We have forwarded your letters to the Board of Examiners, who will doubtless take them into consideration before the next examination.

"*Chemicus.*"—Several recipes for the preparation are given in Beasley's 'Druggists' Receipt Book.'

W. Wilson.—The only notice of which we are aware, is in the second series, Vol. I. p. 42. We expect to be able to give some further information shortly.

"*Pharmaceutist.*"—The fruit of *Physalis Alkekengi* (N. O. Solanaceæ) is slightly acid, and is eaten in Arabia and some parts of the Continent. It is diuretic, and is used in veterinary practice.

Communications, Letters, etc., have been received from Mr. R. C. Mason, Mr. C. S. Miller, Messrs. Paris, Mr. Noble, Mr. Strachan, Mr. A. Tanner, Mr. Rimmington, Mr. Lamb, Messrs. Southall, Son, and Dymond, Mr. J. Abraham, Mr. Weaver, E. B., "Dulcamara," "Aroma."

PHARMACY IN AUSTRIA.*

BY THOMAS GREENISH, F.C.S.

Emerging from Saxon Switzerland on the borders of Bohemia, I recrossed the Elbe, and, after a day spent on the banks of this charming river, found myself in the fine old city of Prague. Here it was that I was first brought into contact with Austrian pharmacy, but as the whole of Austria is under one set of political laws for regulating the practice of pharmacy, as well as under one Arzneitaxe and one pharmacopœia, I shall defer my notice of the subject until I get to Vienna. In speaking of North Germany, I remarked that the pharmacies were in external appearance little more than private houses; but in the cities of Austria that I visited the case was different.

Most of the pharmacies in Prague had imposing plate-glass fronts, but no danger signal hung over the door, neither did a coloured carboy throw its glare into the street; the windows were kept studiously clear of everything but a few slips of porcelain, on which were the names of preparations much in demand, or proprietary articles, among which Liebig's Fleisch Extract occupied a prominent place. There is in this city a Pharmaceutical Society for Bohemia, which meets once a month; but it is as yet in its infancy, and possesses only a very small library. Membership is purely voluntary. In Prague there are 16 pharmacies to 180,000 inhabitants.

From Prague I passed on to Vienna. There, the pharmaceutical establishments are for the most part elegant, having windows of plate-glass scrupulously free from all obsolete symbols. One curious feature both in Prague and Vienna is the general use of signs attached to pharmacies, such as prevailed with shops in general in old London; thus—"Apotheke zum Goldenen Hirschen" (Golden Stag). From one generation to another the sign remains the same, however often the business may have changed its proprietor; probably this custom may be advantageous to a business during successive changes.

In Vienna, and also in each of the chief cities of Austria, there exists a pharmacists' Gremium, a legitimate corporation, as old as the pharmacopœia. This is an institution peculiar, as far as my experience goes, to Austria; and as it occupies a very important position with regard to the practice of pharmacy, and the education of the pharmacist, it is well that the distinction should be correctly understood between the Gremium and the Austrian General Pharmaceutical Society.

The Vienna Gremium dates from 1770, and includes all the pharmacists in that city, every pharmacist in Vienna being *ipso facto* a member of it. The same remark applies to the pharmacists of Prague and the other cities as regards their Gremiums. The Gremiums in the different cities are called chief Gremiums; these are independent of each other. There are also smaller Gremiums in the provincial towns, called *Filial* Gremiums, which also are independent of each other, but in connection with the chief Gremium of their district.

The duties of the Gremium are to receive and examine apprentices, discuss trade matters, look after the strict observance of Government regulations, exercise a certain discipline over its members, make proposals and offer advice to the Government, besides making the latter acquainted with the wishes and wants of the body. It never meets for scientific, but only for administrative purposes.

On the books of the Gremium every apprentice is entered as well as every assistant, and the name of the proprietor of every shop is registered. Before the Board of the Gremium the apprentice passes his "Tirocinal" or Minor Examination. This board consists of a president, vice-president, a Government medical officer, and three members, pharmacists, chosen from the Gremium. The president and vice-president are elected by the members for a fixed period, generally three years; they are recognized by the Government as the representatives of the Gremium in any matter connected with the authorities. It is with the Gremium only that the Government confers on matters connected with pharmacy, and it generally applies to that of Vienna. The Gremium meets four times a year, and all pharmacists are of necessity members of it, but they are only connected with the Austrian Pharmaceutical Society in so far as they have voluntarily joined that body.

In all the chief Gremiums there are benevolent funds for distressed members, and also pharmaceutical assistants. In that of Vienna, the fund is about £3500; the members pay together about £80 a year to it, and £250 is spent yearly in affording immediate relief and permanent aid.

In the gymnasia, or classical schools, a youth passes from one class to another by certificate, the result of an examination; the certificate must be signed by the director and all the professors. The candidate for apprenticeship to an apothecary must bring with him his last certificate, showing that he has passed through four classes of the gymnasium satisfactorily. This would comprise such an education as I mentioned in connection with apprenticeship in North Germany. The certificate must be presented to the Board of the Gremium to which the apothecary to whom the candidate is to be apprenticed belongs, and in order to become an apprentice, no further examination is required. The term of apprenticeship is three years, during which time the candidate is engaged in learning practical pharmacy, with time for study, and the opportunity of attending lectures. At the expiration of his three years he is again taken to the Gremium by his principal, and has to pass before that Board his Tirocinal, or Minor Examination.

This examination comprises botany, materia medica, chemical and pharmaceutical preparations. He must also read and translate prescriptions, and give proof of practical skill in pharmacy. Having passed this examination, he receives a certificate, signed by all the examiners, with the seal of the Gremium attached to it. He now becomes an assistant, in which capacity he must serve two years in a shop, but he cannot yet become the proprietor of one; and for every young man in an establishment with this qualification only, the proprietor is responsible.

At the expiration of two years thus spent, the assistant acquires the right of attending lectures at the university, where he must remain two years or four sessions. In the first year he takes mineralogy, botany, zoology, and physics. At the expiration of his first year, he must pass an examination entitling him to enter the second year's classes

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, May 1, 1872.

In the second year he takes pharmacognosy, chemistry,—analytical, organic and inorganic,—and pharmaceutical legislation, together with laboratory work. At the end of the second year he undergoes his second examination; if successful, he receives his pharmacist's diploma, which entitles him to undertake the independent direction either of the establishment in which he has served, or of any other, or he can establish a new business if he gets the Government concession.

There is an annual visitation of pharmacists' shops. In university towns the commission for that purpose consists of the Dean of the medical faculty, the professors of botany and chemistry, and the two presidents of the Gremium. The result of the examination is noted in a protocol, which is signed by the examiners, and countersigned by the proprietor of the shop, and always forwarded to the Government. In smaller provincial towns the examination is made by the Government medical officer alone. The fee for such an examination is six ducats, or £2. 14*s*. for university towns, and three ducats for smaller ones. If the result be unsatisfactory, a second examination takes place after a short interval, and for this another fee has to be paid by the unfortunate proprietor. Pharmacists in Austria think it very hard that they should have to pay for an examination made solely in the interests of the public

In Vienna there are fifty-nine pharmaceutical establishments to 600,000 inhabitants. It is curious to notice the different customs that prevail as regards dispensing. In England, as a rule, great care is taken to put an external application into a blue bottle, and label it with a coloured label. In Austria there is no difference made between external and internal medicines, either in the shape of the bottle or the colour of the label. Even if the bottle contains a poison, it is not permitted, by attaching a poison label, to inform the patient that the lotion prescribed by the physician contains a poison; neither is it permitted to translate a prescription for a patient. In fact, in Austria it is thought that we have made a mistake in printing the British Pharmacopœia in English, and some English pharmacists are of the same opinion.

Assistants have usually two half-days a week for recreation, and apprentices two hours or so every day for study.

I shall now pass on to the formation of the Austrian General Pharmaceutical Society. It was somewhere between 1830 and 1840 that the chemists of Austria first began to form themselves into a society, but in 1848, the year of the revolution, the society then existing at Vienna was closed by order of the Government. Great efforts continued to be made to get a concession for a general society of the pharmacists of Austria, and it may be said that it was not until 1860 that the Minister of the Interior acknowledged the statutes of the Austrian General Pharmaceutical Society. It has now been in existence eleven years, and numbers between 500 and 600 members from different parts of Austria. Its museum contains a large collection of materia medica, drugs, chemicals, minerals, etc. Its collection of cinchona barks is specially valuable; that of woods, more especially of the Coniferæ from America, of which there are about 200 specimens, very interesting; and its herbaria of plants extremely useful to the young students. These are all so admirably arranged, so neatly and accurately labelled, with printed catalogues of reference, that it reflects the greatest credit on this society. I may add also that all this has been accomplished as a labour of love by pharmacists who have retired from business. A laboratory also has just been completed, in which instruction is given to students; it is not intended for pharmacists alone, but also for meeting the wants of the public by the analysis of water, urine, soils, etc.

In the rooms of the Society lectures on chemistry, botany, and materia medica are delivered to apprentices three times a week. The Society holds annual meetings; every third year it meets in Vienna, and in the intervening years in one or other of the chief cities, such as Prague, Brunn, etc. The membership of this body being voluntary, and its annual general meetings being held in different cities, it approximates more nearly to our Pharmaceutical Conference than to our Pharmaceutical Society. There are separate Pharmaceutical Societies in Prague, Gratz, Lemberg, etc., but little attention is paid by them to scientific subjects; they deal chiefly with the social and business interests of the members, and do not, like the Vienna Society, provide lectures for apprentices.

Through the kindness of Mr. Hills I was favoured with an introduction to Mr. Waldheim, to whose courtesy I am much indebted. He is President of the Gremium, and Vice-President of the Austrian Pharmaceutical Society; and while he holds these positions neither the interests of pharmacists or of pharmacy are likely to suffer. It is hoped that an important alteration in the Apothekerordnung will be secured. At present, questions affecting pharmacy are determined mainly by medical men and chemists; and the alteration looked for in the new Apothekerordnung is that on all matters affecting the interests of pharmacy, pharmacists themselves may be largely represented and have more influence. In fact, great efforts are being made by the body to shake themselves free, and to show themselves worthy of freedom.

From Vienna I went down the Danube to Pesth, in Hungary. This city has a population of about 200,000, and 14 pharmacies; while Ofen, or Buda, on the opposite side of the river, has ten pharmacies to 58,000 inhabitants. Hungarian pharmacy, I am informed, is much behind that of Germany; at present the Austrian Pharmacopœia is used, but a hope was expressed to me by a Hungarian pharmacist, that they would soon have a pharmacopœia for Hungary; and considering, that of the mixed population of the Austrian Empire, Hungary numbers about ten millions, and also that Hungarian counsels have prevailed with the Austrian Government, it is quite possible that they may succeed in their wishes.

After Pesth I went to Salzburg, with its 20,000 inhabitants and four pharmacies, but this is not a place of sufficient importance to require any notice.

With Salzburg my inquiry terminated, and I returned through South Germany, the pharmacy of which I left to a more convenient season. Having time for reflection on my homeward route, I asked myself what were the impressions left on my mind by this inquiry into the condition of pharmacy in North Germany and Austria; whence this great excellence in the German Pharmacist. In education, scientific attainments, and social position, he appears to shadow forth the Pharmacist of the future for Great Britain. It appeared to me, in the first place, that the sound education required of the candidate for apprenticeship was very important; while at school he can only rise from class to class by undergoing an examination, and it is only after he has passed through four classes that he can obtain the certificate without which he is not received as an apprentice. In the next place, during his three years' apprenticeship—and three years is ample time for apprenticeship—he is allowed two hours a day for study, and his employer is required by the Apothekerordnung to assist him in his studies, by providing him with books and instruction. The employer is reminded that there are duties as well as rights, trouble as well as profit, in the proper education of the apprentice. Whilst on this subject I will read some very pertinent remarks from the Prussian Pharmacy Laws, which merit careful attention by those who take apprentices.

"All apothecaries may take apprentices, but as they sometimes study their own advantage more than they do that of the apprentice or the public, the following has been made binding:—They must only take such apprentices as have by nature good parts, and as are sufficiently prepared by education and good moral training. In order that apprentices may not be taken from school too soon, it is enjoined that they do not leave before the age of 14; and as the knowledge of the Latin language is indispensable for properly understanding prescriptions, no apprentice shall be taken until he can translate easy passages from a Latin author. The decisions shall not be left to the masters themselves, but it shall be their duty to let the *intended* apprentice be examined by the Government Medical Officer. The master has further to see that the intended apprentice writes fluently and distinctly; this is particularly necessary to prevent mistakes occurring and the patient being misled by illegible writing.

"It is the duty of the master to provide proper books for the apprentice. It has occurred that apothecaries in many places have had other business than that of an apothecary to attend to, and that sometimes they have no *assistant*, but only three or four apprentices instead, and they prefer to take the roughest and most ignorant of boys, and also those that are too young, because they could make use of them for the rough work in their other businesses; and as the practice has led to an increase in the number of mere mechanical chemists' assistants, it is hereby ordered that an apothecary be allowed to take only as many apprentices as he has qualified assistants. If the business be so inconsiderable that one person only be employed, then no apprentice can be taken unless it be impossible to procure an assistant, or that the master be sufficiently skilful to take the place of assistant.

"To prevent the increase of badly trained assistants, it is ordered that for the future no master shall give his apprentice a certificate until the said apprentice has been examined by the Government medical officer in the presence of his master. The examination shall refer to such subjects as he has a right to expect from so young a man. He shall be particularly examined as to his practical knowledge of pharmacy and handiness in doing ordinary work, as practical knowledge is of more importance than mere theory in an apothecary. Should it be found that he is not yet a capable assistant, it is the duty of the Government medical officer to inform him that he cannot yet leave his apprenticeship, but must remain until he has fully qualified himself. Should it, however, appear that the master is more in fault than the apprentice and that he has neglected him or shown his own incapacity to instruct him in the business of an apothecary, that master shall be forbidden to take another apprentice."

Then again, the Minor examination is a qualification for an assistant only; he cannot conduct the business in the absence of the principal, neither can he purchase a business for himself. Our Minor, less thorough in its character, and less crucial, is a qualification for business as a chemist and druggist. But those who believe that pharmacy is progressive must arrive at the conclusion that an alteration here is only a question of time. After the Minor, three years must be spent in the practical details of pharmacy, and then the assistant goes to the university. Here lectures with practical work occupy his time, and after two severe examinations he procures his diploma, a qualification which enables him to conduct a pharmacy.

It will be noticed that in the examinations both of North Germany and Austria a knowledge of those political laws which govern the practice of pharmacy is required of the student; and in practice he does understand the letter and spirit of those laws. In this country when questions arise immediately affecting the interests of pharmacists, it is not until the danger is at our door that the body at large can be made to understand them. Our position, as defined by the several Pharmacy Acts and Poison Regulations, is so imperfectly understood, that our strength, as a body, is weakened, and our influence diminished. In the old Apothekerordnung, it was imperative that every pharmacy should have a laboratory attached to it; this brought into existence small apparatus suitable to the requirements of a pharmacist desirous of making the preparations of the pharmacopœia for his own establishment, a want much felt in this country where our pharmaceutical engineers cannot be made to understand that an ordinary room may suffice for a very efficient laboratory, where an acre of ground is not available.

I hold it to be the bounden duty of every one that takes an apprentice to teach him, or cause him to be taught, to make every preparation in the British pharmacopœia, and this may be done at a very moderate outlay. He should also be taught the history of most of the substances which constitute our materia medica, as well as how to recognize them.

In every city and town in North and South Germany, and also in Austria, the number of pharmacies is limited by Government regulation; it averages one pharmacy to about 10,000 inhabitants, and unless the population very much increases, no addition is made to the number. When there exists an apparent necessity, an addition can take place by Government concession. The pharmacists having this privilege are obliged to charge all drugs, and dispense medicines according to the price in the Arzneitaxe. This name may convey to the British pharmacist an erroneous impression as to its use; it is not a tax, but a medicine price-list. To give you an idea as to its working, I will take this prescription:—

Acid Tannic 0·1
Opii Puri 0·025
Sac. Alb. 0·3
Dos. x.

	Pfennige.
Acid Tannic 1·0	3
Opii Puri 0·25	1·0
Sac. Alb. 3·0	3
Mixing the powder	8
3 weighings	2
Dividing the powder (3 pfennige each)	3·0
Box with gold label	2·3
	7·9*

This limitation of pharmacies by Government is the question of the day throughout Germany. There is in Berlin an Apothecaries' Assistant Society which is now working vigorously for the abolition of this privilege, while on the other hand, the pharmacists already in business are battling hard against the proposed freedom of trade.

I fear that these hasty sketches of pharmacy in North Germany and Austria, the results of a holiday ramble, are very imperfect, but they may serve to direct attention to what our colleagues are doing in that part of the Continent. Germany, as regards pharmacy, is on the eve of important changes. This month the 'Pharmacopœia Germanica' will be published; on the 1st August it will come into force throughout the whole of Germany, and in September of this year, the general meetings of the North German Pharmaceutical Society, numbering 14,000 members, and the South German Pharmaceutical Society will take place conjointly at Frankfort. The question of the amalgamation of the two societies, and of the acceptance, by the latter, of the statutes of the North German Pharmaceutical Society, will be raised and discussed. There will then be for the whole of Germany one State pharmacopœia, one code of pharmacy laws, one arzneitaxe, and one pharmaceutical society. In Austria, also, pharmacists are by no means idle; and throughout the whole of North Germany and Austria, the educational standard for pharmacists is being raised rather than lowered. The following is an extract from a letter which I have received from Dr. Schacht, of Berlin:—

"In 1872, we hope that the education of pharmacists in Prussia and in the whole of Germany will be as follows:—

"After three years' apprenticeship (half a year of apprenticeship being dispensed with if the candidate has occupied the first class of the Gymnasium), he will pass his Minor before a Government medical officer, and a pharmacist. This examination lasts one day, and will be practical and theoretical; he will have to make certain preparations, and he must possess some knowledge of the *laws which govern pharmacy*. He will have been three years apprentice, three years assistant, and two years at the University, and then be examined. Then he will have to serve one year in the army, during which time he may be a soldier, or an apothecary to the army. After nine years from the time of his apprenticeship, and having passed the examinations named, he will, as far as qualification is concerned, be in a position to purchase a business."

After a month's absence, with renewed mental vigour, and restored bodily health, I returned home to grapple with the present, and dream of the future of British pharmacy, which, unaided by the same special protection, but untramelled by over-legislation, will rise to its proper place among the pharmacies of Europe, enriching science with fresh discoveries, and returning some of those benefits of which it has hitherto been for the most part only a thankful recipient.

[*The discussion upon this paper is printed at p.* 894.]

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

(*Continued from page* 848.)

(2.) It being assumed that the molecules of codeia and morphia contain respectively either C_{18} and C_{17} or C_{36} and C_{34} (which latter is probably the case, experiments now in progress indicating that the molecular formulæ of these bases are double those usually ascribed to them), the above experiments lead to the conclusion that there exist polymerides of these alkaloids containing C_{72}, C_{144}, ... , or C_{68}, C_{136}, ... , these polymerides being formed by the action of strong acids, and serving as starting-points for new series of derivatives; experiments to obtain these polymerides in an unaltered condition are, as has been previously stated, in progress, and apparently with success.

This facile disposition to form polymerides is not an unknown feature in alkaloids, the experiments of Anderson having shown that the pyridine bases are characterized by this property; this fact would appear to warrant the speculation that morphia and codeia contain carbon groups analogous to, if not identical with, those contained in the pyridine bases; and, in fact, experiments now in progress, in conjunction with Herr L. Mayer, apparently lead to the conclusion that pyridine is obtainable from morphia derivatives by treatment which, though energetic, is nevertheless far short of destructive distillation: indeed, it may be doubted whether the carbon groups contained in the pyridine series of bases do not pre-exist in the bodies from which these bases are obtained by destructive distillation.

(3.) A comparison between the formulæ of the products obtained by the three hydracids HCl, HBr, and HI shows that while the action of HCl is simply to replace OH by Cl, or to remove the elements of H_2O (sometimes also replacing CH_3 by H), that of HBr is (in addition to the changes produced by HCl) to cause the addition of hydrogen to that one of the two resulting products that is derived from the non-polymerized molecule. Thus—

HCl and codeia give $C_{17}H_{17}NO_2$, apomorphia,
HBr ,, ,, $C_{17}H_{19}NO_2$, deoxymorphia,
which may be represented as $C_{17}H_{19}NO_3-H_2O+H_2$.

This hydrogenizing action is carried still further in the case of the derivatives obtained by HI; thus the expressions—

$$4C_{17}H_{19}NO_3-2H_2O+2HI+H_8,$$
$$4C_{17}H_{19}NO_3-6H_2O+2HI+H_{16}$$

represent the composition of the bases obtained respectively from morphia and codeia at 130°.

(4.) Codeia appears to be a species of methylic ether of morphia, their relative constitutions being probably—

$$C_{17}H_{17}NO\left\{\begin{matrix}OH\\OCH_3\end{matrix}\right. \text{ and } C_{17}H_{17}NO\left\{\begin{matrix}OH\\OH\end{matrix}\right.$$

(doubling the formulæ will not alter their relations in this respect). Adhering to the formula hitherto employed, the production of the same apomorphia from both alkaloids is readily accounted for thus:—

$$C_{17}H_{17}NO \left\{ \begin{matrix} OH \\ O.CH_3 \end{matrix} \right. + HCl = C_{17}H_{17}NO \left\{ \begin{matrix} Cl \\ O.CH_3 \end{matrix} \right. + H_2O,$$

Codeia. Chlorocodide.

$$C_{17}H_{17}NO \left\{ \begin{matrix} Cl \\ O.CH_3 \end{matrix} \right. = \left. \begin{matrix} Cl \\ CH_3 \end{matrix} \right\} + C_{17}H_{17}NO \left\{ O'', \right.$$

Chlorocodide. Apomorphia.

$$C_{17}H_{17}NO \left\{ \begin{matrix} OH \\ OH \end{matrix} \right. = H_2O + C_{17}H_{17}NO \left\{ O''. \right.$$

Morphia. Apomorphia.

According to this view morphia should contain two hydroxyl groups for every C_{17}, and codeia only one. Experiments are contemplated, with reference to this point, on the action of aniline, acetyl chloride, and glacial acetic acid, on these alkaloids, whereby it is hoped that definite information may be gained as to the presence, or otherwise, and the number of the groups CHO (aldehyde group), OH, etc.

(5.) It appears not improbable that codeia and morphia may contain in their molecules benzene residues. Schiff has pointed out* that phenols give colourations with ferric chloride, whereas the corresponding ethers or anisols do not do so; the well-known distinction between morphia and codeia in this respect, therefore, gives some support to the idea that both may be benzene derivatives.

III. *On the Physiological Action of some of the foregoing Derivatives.* By Reginald Stocker, M.B., Pathologist in St. Mary's Hospital Medical School.

Doses of one decigramme of the compound

$$C_{68}H_{81}I_2N_4O_{10},4HI$$

from codeia, and of the similar compound from morphia, were given to an adult terrier by the mouth without producing any perceptible effect whatever; when the dose was increased to three decigrammes, in each case repeated defæcation in the course of a few hours was produced, the stools being more loose than ordinarily and frequently of a dark greenish colour; no other symptom was noticeable, and no appreciable difference in the action of the two compounds was perceptible.

Doses of 5 decigrammes of the compound

$$C_{68}H_{82}I_2N_4O_{10}.4HI$$

from each of these sources were given to the same dog by the mouth with the result of producing similar repeated defæcation in the course of two or three hours; the sole difference discernible between these and the former experiments being that the effect was produced somewhat sooner and was of longer continuance in the latter cases, a result probably produced solely by the larger dose. No material differences were observed between the codeia and morphia derivative.

The same dog was employed throughout, two or three days being allowed to intervene between each experiment, so that the animal had recovered from the effects of a former dose before the administration of another.

It would hence appear that the derivatives of polymerized $C_{17}H_{21}NO_3$ are less active than those of polymerized $C_{17}H_{19}NO_3$; and also that there is no reason for considering the derivatives from codeia as different from those of morphia, the corresponding bodies having respectively the same quantitative composition and the same physical, chemical, and physiological properties.

Part V.

I. *On the Polymerides of Codeia.*

In Part IV. of these researches reasons have been adduced for the following general conclusions, viz., that codeia and morphia are capable of forming polymerides (with the elimination of methyl in the case of codeia in some instances), which yield derivatives containing certainly not less than C_{68}, and probably not less than C_{136} (C_{72} and C_{144} in the case of those codeia derivatives where methyl has not been eliminated). Experiments now in progress tend to show that the formulæ of codeia and morphia are really double of those formerly ascribed to these bases, *i.e.*, are

$$C_{36}H_{42}N_2O_6 \text{ and } C_{34}H_{38}N_2O_6$$

respectively, the proof of which is (as will be shown in a subsequent communication) that the first products of the action of hydrochloric acid on these bases appear to contain chlorine and carbon in the proportions C_{36} and Cl, C_{34} and Cl respectively, instead of C_{18} and Cl, or C_{17} and Cl. It might be anticipated, therefore, that intermediate polymerides might be formed containing respectively,

Morphia Series.			Codeia Series.
Monomorphia...	$C_{34}H_{38}N_2O_6$	... $C_{36}H_{42}N_2O_6$	Monocodeia.
Dimorphia	$C_{68}H_{76}N_4O_{12}$	... $C_{72}H_{84}N_4O_{12}$	Dicodeia.
Trimorphia	$C_{102}H_{104}N_6O_{18}$	... $C_{108}H_{126}N_6O_{18}$	Tricodeia.
Tetramorphia...	$C_{136}H_{152}N_8O_{24}$	... $C_{144}H_{168}N_8O_{24}$	Tetracodeia

In the case of codeia these anticipations have been verified.

In order to obtain these supposed polymerides before their further alteration by secondary reactions, the action of acids other than the hydracids was examined. Acetic acid seemed a probable agent for this purpose; but no appreciable quantity of anything different from ordinary codeia was obtained after sixty-four hours' digestion at 100° of one part of this base with three parts of glacial acetic acid. On precipitation of the product by Na_2CO_3 in large excess, extraction with ether, and agitation of the ethereal extract with HCl, a crystalline mass was obtained which developed a smell of acetic acid on standing in contact with a slight excess of HCl; but on analysis this gave numbers agreeing with those required for codeia hydrochlorate, and from it nothing different from codeia could be obtained; probably, therefore, only a trace of acetyl-codeia was formed.

The action of phosphoric acid, however, was found to lead to the desired result without the formation of by-products beyond colouring-matters formed by the high temperature employed; by heating codeia with three parts glacial phosphoric acid and 5 of water for several hours at 100°, no perceptible change is produced. The same result follows on boiling for twelve hours (boiling-point 105°) with an inverted condenser attached to prevent loss of water by evaporation; but if the boiling-point be allowed to rise slowly from evaporation, the mixture being very gently boiled in a long-necked flask, the product gradually acquires the power of giving an immediate amorphous precipitate with Na_2CO_3; no large amount of new substances are, however, formed until the boiling-point has risen to about 200°, beyond which point the evaporation cannot safely be pushed. The viscid chestnut-coloured liquid, while still hot, is dissolved in boiling water and allowed to cool; nothing separates on cooling; when cold, the liquid is nearly neutralized by caustic soda, and then precipitated with Na_2CO_3; the precipitate is collected on filters, drained from mother-liquors, dissolved in weak HCl, and reprecipitated by Na_2CO_3, to get rid of traces of unaltered codeia mechanically retained; finally, the drained precipitate is exhausted with ether. The ethereal solution yields on agitation with HCl a crystalline hydrochlorate, which may be purified by solution in water, fractional precipitation with Na_2CO_3 and repetition of the ether process, and finally, by re-crystallization of the resulting hydrochlorate.

(To be continued.)

MEETING AT HULL.

A meeting of the members of the Pharmaceutical Society of Hull was held at their room on Tuesday, April 30th.; Mr. A. Pickering, President of the Hull Chemists' Association in the chair.

It was unanimously resolved to support the list of fourteen names proposed by the United Defence Association.

* Ann. d. Chem. u. Pharm., vol. clix. p. 518.

THE PROPOSED DINNER AT THE CRYSTAL PALACE.

With the view of affording the members of the Pharmaceutical Society, and old pupils of the School of Pharmacy, who may come to London to attend the Annual Meeting on the 15th May, an opportunity of meeting their fellow-members in the metropolis and other friends, a Public Dinner will take place at the Crystal Palace on Tuesday, the 14th of May, at six P.M.

The PRESIDENT in the chair.

STEWARDS.

Allchin, A., London.	Linford, J., London.
Atherton, J., Nottingham.	Mackay, John, Edinburgh.
Attfield, Professor, London.	Mackey, J. B. London.
Barron, F., London.	Martindale, W., London.
Betty, S. C., London.	McCulloch, F., London.
Bottle, Alex., Dover.	Malden, W. W., London.
Bremridge, Elias, London.	Paul, Dr., London.
Barnes, J. B., London.	Preston, Alfred, London.
Bentley, Professor, London.	Redwood, Professor, London.
Brown, W. S., Manchester.	Robbins, John, London.
Bourdas, J., London.	Radley, W. V., Sheffield.
Burden, E., London.	Sandford, G. W., London.
Cracknell, C., London.	Savory, C. H., London.
Deane, Henry, Clapham.	Squire, William, London.
Davenport, J. T., London.	Shaw, Jno., Liverpool.
Down, Dr. Langdon., London.	Smith, E., Torquay.
Evans, H. S., London.	Stoddart, W. W., Bristol.
Frazer, D., Glasgow.	Schacht, G. F., Clifton.
Gale, S., London.	Southall, W., Birmingham.
Greenish, T., London.	Starkie, R. S., London.
Giles, R. W., Clifton.	Schweitzer, J., Brighton
Haselden, A. F., London.	Tilden, W. A., D.Sc., London.
Hill, A. B., London.	Urwick, W. W., London.
Hills, T. H., London.	Wade, Jno., London.
Hodgkinson, W., London.	Williams, Jno., London.
Hampson, R., London.	Warrick, R. B., London.
Howden, R., London.	

Gentlemen willing to act as stewards will oblige by forwarding their names to the Hon. Secretary. Dinner tickets, including wine, one guinea each.

In order to make the necessary arrangements and prevent discomfort, members and *their friends* desirous of being present are requested to apply *at once* for tickets, enclosing a P. O. O. for the amount, to Mr. BREMRIDGE, 17, Bloomsbury Square, W.C., or the Hon. Sec., MICHAEL CARTEIGHE, 172, New Bond Street, London, W.

Grenadier Guards' Band under the direction of Mr. Dan Godfrey.

THE EARLY CLOSING MOVEMENT AT CHELTENHAM.

A Meeting of the Chemists and Druggists of Cheltenham was held on the 25th April, to take into consideration the following memorial of the assistants and apprentices in their employ:—

"Gentlemen,—We, the assistant chemists and apprentices of Cheltenham, viewing with satisfaction the success which has attended the efforts made in some of the principal trades in the town, to diminish the hours of labour during the summer months, most respectfully pray you, our employers, to reduce the hours of business in our profession.

"We feel we can venture to ask this, not only on account of a want of sufficient time for physical and mental recreation, but also because of the higher educational demands which the late Pharmacy Act imposes upon us.

"We most respectfully beg to suggest that the hours of closing least likely to operate with disadvantage to the trade or the public, will be five o'clock on each Wednesday, and eight o'clock on other evenings, throughout the summer,—from the beginning of April to the end of September."

The following resolution was proposed, seconded and carried unanimously:—

"That this meeting, while desirous of shortening the hours of business, and of joining, as far as circumstances will admit, in any generally adopted arrangement, on the part of the various trades of the town to attain that object, regrets its inability to meet the request of the assistants and apprentices, so respectfully stated in their address to the chemists of the town."

THE VISIT OF THE BRITISH PHARMACEUTICAL CONFERENCE TO BRIGHTON.

A Meeting of the Chemists and Druggists of Brighton was held at the Town Hall on Wednesday, April 24th, under the presidency of Mr. W. D. SAVAGE, with the object of discussing what steps should be taken in reference to the projected visit of the British Pharmaceutical Conference in August next. It was unanimously decided that the Pavilion Committee should be communicated with respecting a suitable room where papers might be read and the Conference business transacted. It was also resolved that a dinner should be given to their *confrères* at the close of the first day's business; and that on a subsequent day, provided the weather be favourable and a sufficient sum of money be raised, to organize a picnic to the Dyke. The treasurer, Mr. Thomas Glaisyer, reported favourably of the response to his appeal for funds, and said that further communications would be made to the local secretaries at Lewes, Hastings, Eastbourne, Worthing, Horsham and other places.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The Annual Dinner of this Association took place on Thursday, April 25th, at the Mitre Hotel. Covers were laid for thirty. After the repast the Secretary's report was read. The usual toasts followed which, with music and songs, concluded this thoroughly enjoyable social reunion.

The General Meeting (for the election of officers for the next session) is postponed owing to the removal from the rooms recently used by the Association.

LETTER ON PROVINCIAL EDUCATION.

The following copy of a letter sent to the Presidents of several Provincial Associations who responded to Mr. Radley's communication of February 15th has been forwarded to us by the writer:—

"*Sheffield, April* 30*th*, 1872."

"Dear Sir,—In reference to my former letter on the steps taken by the Council of the Pharmaceutical Society with regard to provincial education, I have to thank you for the prompt manner in which you dealt with it by bringing the subject before your association. The object I had in view was to ascertain the general opinion of chemists in the country on the question, and to take action thereon if it was deemed desirable.

"It is remarkable that my letter struck a chord which immediately vibrated through the body politic, and drew forth a response which betokens a wide-spread dissatisfaction with present arrangements in this particular. No doubt you will have noticed the discussion which took place on this subject at the last meeting of the Council, as reported in the Journal of April 6th, from which it appears the Council is prepared to reconsider the matter with a view to a more liberal use of the funds of the Society in aiding pharmaceutical education throughout the country. This being the case, it seems to me undesirable at present to convene a meeting of delegates of provincial associations, but that a wiser course will be to wait awhile and reserve our strength for future action if the necessity continues. The Annual Meeting will probably afford an opportunity of bringing the subject before the Society. Will you have the goodness to make known the contents of this letter to the members of your Association? and believe me to remain, yours truly,

"W. V. RADLEY."

The Pharmaceutical Journal.

SATURDAY, MAY 4, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE RELATION OF THE PHARMACEUTICAL SOCIETY TO EDUCATION.

THE action of the Pharmaceutical Society in regard to Education is a subject which has recently cropped up from time to time, in these pages, and, in the form either of an address, an essay, a letter, or the report of a provincial association, various opinions have been expressed respecting it. But generally the reference to this subject has been either purely incidental, or so far superficial that only certain of its aspects have been dealt with.

Even the recent idea that the Society should provide educational facilities for students in the provinces does not appear to have excited sufficient enthusiasm to produce any response to our suggestion that it should be discussed in these pages; and though "provincial education" has since assumed a prominence to some extent commensurate with its importance, the expression of opinion on this subject has been almost entirely one-sided. Possibly the majority of our members are satisfied with the present position of the Society in this matter; it is one which has cost much labour, time, and money to mature, and, therefore, it should not be lightly set aside.

On the other hand, there is evidence that many do not understand what the existing relation of the Society to Education really is. Some who have spoken or written on the question evidently labour under considerable misapprehension on this point.

Thus we have, in the first place, one who is a pioneer in the matter treating the Society's School as being simply metropolitan, while another prominent thinker gives the Council credit for promoting the education of provincial men only to the extent to which it has subsidized local effort by small grants. And a third eloquent leader in Pharmaceutical policy evidently regards the School in Bloomsbury as benefiting only London and its suburbs. Now, as a matter of fact, four out of five students in the Society's laboratory are young men who come from the country specially to study there, with the object of passing the Society's examinations, and they return to the country as soon as that object is accomplished. This has, indeed, always been the case.

When, therefore, presidents and members of provincial associations base their arguments for grants in aid of local schools upon the erroneous assumption that the funds expended by the Council on education do not benefit the provinces, they place themselves in opposition to fact, and miss the really cogent argument they might urge in support of their views. The School of Pharmacy, in Bloomsbury Square, is in reality far more provincial than metropolitan; if the provinces have chiefly contributed to its support, the provinces have received the chief benefit. In this respect it resembles most other metropolitan institutions, or, in fact, London itself, which, unlike most other towns, has not been placed in its proud position solely by the energy of its merchants and traders—is not ever striving to outstrip a rival, for it has none,—is, indeed, scarcely a town at all, containing as it does several towns, two cities, and some half-dozen boroughs, but is rather a provincial centre. So the Society's School is the School of Pharmacy of Great Britain, located in the most convenient centre; while in respect of organization, funds and students, it is what the counties generally, and not merely Middlesex and Surrey, have made it.

In short, the members of the Pharmaceutical Society have successfully established one central school of which all are proud. We might, moreover, add that London, the centre at which all English candidates for examination attend, offers extra-collegiate facilities for pharmaceutical study at least equal to those of any town in the kingdom. But we refrain from multiplying such arguments, as our object is not to plead for the present school, but to state its true position in regard to metropolitan and provincial members of the Society. It is a question whether the advantages it offers are fully appreciated by all; but certainly they are not made use of as they should be, even by those who cannot plead the excuse that it is inaccessible; and though it may be matter for argument whether a second or third school of similar character should be founded elsewhere, it is much more a question of urgency to consider whether in view of the great difficulties of creating such establishments—comprising not only a lecture-room, laboratory, store-rooms, and other offices, but also a museum, library and professorial staff—it might not be desirable to endeavour to get more work out of the existing school, for its appliances are ample, for very much larger classes than have yet attended the Institution.

In saying this much, however, it must not be supposed that the importance of what is generally meant by the term "provincial education" is undervalued, or that the need for further educational facilities in the provinces is in the least doubted. Apart from other evidence, the action lately taken by several provincial associations fully proves the existence of a want in this respect, as well as the imperative necessity of providing for that want; and the question now to be considered is simply what part the Pharmaceutical Society should take in that direction.

Since the time when the Society's educational action assumed its present form, the general conditions to which the business of pharmacy is subject have been so far legislatively altered that there is, indeed, on this account alone, ample reason for reconsidering how far that action is sufficient or appropriate under existing circumstances; and it must be remembered that since the Society is now acknowledged as the governing power for the entire trade, it is not only in regard to members that its functions, in this respect or otherwise, have to be considered.

Regarding the subject from this point of view, and assuming that the attendance at the lectures and laboratory in Bloomsbury Square were very much more numerous than it ever has been, it may, nevertheless, be taken for granted that a very large majority of those who require pharmaceutical education could not come up to London for the purpose. To meet their case it would be necessary that they should have access to lectures during the time of their apprenticeship or while acting as assistants. But any measures taken to provide such a general system of teaching must evidently apply to the entire trade; and although it would be eminently in accord with the spirit of the Society's charter to promote such an uniform system of education, the fact that only about one-fifth of the trade are connected with the Society raises a difficulty as to the application of the Society's funds to the purpose. For this reason there seems to be some irrelevancy in the argument put forward by Mr. Baynes, Mr. Radley and others, that grants should be made to provincial associations as a return for the support heretofore given by country members to the Society. That argument might have considerable force as regards those connected with the Society, but it could not well be urged as a reason for the Society granting money to support provincial schools, unless at the same time it were seconded by the offer of liberal contributions from those who are not connected with the Society. Thus taking, for instance, the towns of Leeds, Sheffield and Hull, where the subject of provincial education has been very prominently mooted, it appears that the great majority of pharmacists in those towns do not belong to the Society. Even the number of registered apprentices and associates is far less than might have been expected, as will be seen from the following table:—

	Leeds.	Sheffield.	Hull.
Total number in business	112	100	102
Connected with Society	27	27	19
Associates not in business and Registered Apprentices	11	9	4

It is, therefore, an important point to ascertain how far any effort to establish provincial schools would be aided by the whole or even the majority of those in the trade. In regard to this point, we regret that so little has been done to carry out the suggestions offered in a previous article* on the subject, that our provincial friends should, by taking stock of their local wants and resources, ascertain what prospect they have of keeping up schools of pharmacy, as well as the means they can command for the establishment of such schools; but we hope the disposition since shown by the Council to deal with this subject in a liberal manner will yet be the means of bringing about such a course as we then suggested.

At the same time, we unhesitatingly deprecate the idea of making the provision for pharmaceutical instruction in any way partake of an eleemosynary character. In starting provincial schools, there probably must be, in many cases, some expenditure which cannot be at once recouped; but we have no faith in the utility of attempting to establish such schools, unless there be some decisive evidence that they will continue to be self-supporting. It is, moreover, very important to bear in mind that this condition has never yet been attained by our existing school.

Taking the general result of such attempts as have been made, it is too apparent that the aid required by "provincial education" is not so much money as interest on the part of those requiring to be taught.

Without dwelling too much on the failure that has characterized most attempts to establish schools of pharmacy in the provinces, it would be unwise to overlook this fact. It would be equally unwise to ignore the indifference to the claims for education prevailing in many cases among country chemists, or to disregard the disinclination of young men to enter upon the serious study of those subjects which should be mastered by every one who hopes to follow with credit the career of a pharmacist even in its most humble form.

How those obstacles are to be removed is a question well deserving the earnest consideration of every one desirous to raise the general status of the trade, and we hope those who have been active in making known the need of further educational facilities will, at the ensuing meeting, render the still greater service of demonstrating that there is also such a demand for them as would justify a liberal use of the Society's funds in promoting their establishment throughout the country.

An address from the students attending the class of practical chemistry at the Royal Veterinary College, has recently been presented to Professor Richard V. Tuson, expressing their appreciation of the advantages resulting from laboratory instruction, and congratulating him upon being the first to establish such a course in connection with that college.

The Annual Oration before the Medical Society of London will be delivered on Monday evening next, at the Architectural Society's rooms, Conduit Street, by F. J. Gant, Esq., F.R.C.S., upon "Modern Surgery as a Science and an Art." After the address a conversazione will be held.

---

* Pharm. Journ. 3rd Ser. Vol. I. p. 388.

VOTING PAPERS.

We are requested to call attention to the Special Notice appearing in the front page of the Journal in conformity with a resolution of the Committee to which the matter was referred by the Council, and to point out that, in several instances, the list of candidates recommended by the Chemists' Defence Associations has been mistaken for the official voting paper of the Society and sent in to the Secretary under that impression.

ANNIVERSARY DINNER.

We have much pleasure in referring our readers to page 886 for particulars respecting this new feature of the Society's annual reunion, for which also we confidently ask the same enthusiastic co-operation which has made the Chemists' Ball and the Conversazione so eminently successful. Apart from the pleasurable attractions of the proposed dinner at the Crystal Palace, it has also a utilitarian recommendation which may not be unimportant for the general interests of the trade.

It is an old saying, that to put an Englishman in a good temper the best plan is to give him a good dinner, and though, happily, we do not for a moment suppose the promoters of the dinner can have for an ulterior object the smoothing of any possible difficulties at the coming Annual Meeting of the Pharmaceutical Society on the following day, we know no better plan of eliminating asperities from projected orations than that of giving intending speakers and voters an opportunity of becoming better acquainted, and appreciating the motives by which each is swayed.

The list of stewards given on page 886 comprises names representing every shade of opinion and the fact that so many have readily come forward to aid in making the dinner a success may well be accepted as evidence that the differences of opinion occasionally manifested amongst the Pharmaceutical body have their origin in the earnest desire for the general welfare. We hope the anniversary dinner of the Society will not only be successful this year but that it may also become a permanent institution.

A writer in the *American Journal of Pharmacy* calls attention to the great advances that have been made in the art of disguising nauseous drugs, and attributes to a great extent the increase in the number of votaries of homœopathy to the skill with which homœopathic practitioners have availed themselves of the resources of "elegant pharmacy" in their medicinal preparations. Premising that much might be done by the united action of the allopathic practitioner and the pharmacist to produce medicines that should successfully compete with homœopathic remedies in simplicity, beauty and adaptability, he suggests the abnegation of secret formulæ, on the ground that what is advantageous for one should be for all, especially with regard to such things as remedies for suffering humanity. It is to be feared that while the love of the "almighty dollar" is so strong in both countries, stronger arguments will have to be used to accomplish the desired object.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

May 1st, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. EDWARDS, VICE-PRESIDENT.

Present — Messrs. Atherton, Betty, Carr, Frazer, Greenish, Groves, Hills, Sandford, Savage, Shaw, Smith, Stoddart and Williams.

The minutes of the last meeting were read and confirmed.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted a Diploma stamped with the seal of the Society:—

Dale, John .... Birmingham.
Hill, William Edward .... Leicester.
White, William Edwin ...... Dover.
Wilson, John Herbert .... Harrogate.
Wright, Thomas .... Leicester.

Resolved—That the following Pharmaceutical Chemists be, and are hereby, elected Members of the Society:—

Freeman, Ernest .... Ledbury.
Hill, William Edward .... Leicester.
Southwell, Charles Henry .... Boston.
Towerzey, Alexander .... Clifton.
Ward, Joseph .... Gloucester.
Wilson, John Herbert .... Harrogate.
Woolley, Harold .... Manchester.
Wright, Thomas .... Leicester.

Resolved—That the following registered Chemists and Druggists be elected to Membership:—

Alexander, John .... Liverpool.
Cornforth, Edwin .... Birmingham.
Chalmers, John .... Dundee.
Denston, John Thomas .... Kettering.
Evans, Edward .... Sheerness.
French, Benjamin .... Gosport.
Pitman, John .... Bristol.
Riddle, Joseph .... South Shields.
Rogers, Sampson .... Shaldon.
Salter, Joseph Birch .... Shrewsbury.
Shorrock, Ralph .... Over Darwen.
Stanley, Robert Swan .... Southwell.

Resolved—That the following, having passed their respective Examinations, be elected "Associates in business:"—

Minor.

Brewis, Thomas .... Amble.
Davison, John .... West Hartlepool.
Dolman, William .... Cheltenham.
Evans, Richard Morgan ...... Blaenavon.
McNeil, James Norton ...... Crewe.
Margetson, James Francis .... Coltishall.
Mountain, Robert .... Harrogate Wells.
Palmer, Francis .... Upper Norwood.
Robeson, Charles Brunting.... Southwark.
Stokes, Walter Edward ...... Brompton, Kent.
Wilkes, John Sanders ...... Leicester.
Williams, William Francis.... Chepstow.
Woolstencroft, Joseph .... Northwich.

Modified.

Chapman, Josiah Thomas .... Manchester.
Ellis, Alexander .... Skelton in Cleveland.
Field, Henry .... Aylesbury.
Gibson, Reuben Leonard...... Loughborough.
Graves, Joseph Waddington .. York.
Grimditch, William James .. Ely.
Highley, William .... Rochdale.
Morgan, Philip Henry .... Taunton.
Passingham, George William .. London.
Radclyffe, Robert Caygill Tom Birmingham.

Sloman, Richard ....Torquay.
Smith, Percy John ....Balham.
Spratt, George Uriah ....Nottingham.
Woodcock, Arthur ....Norwich.
Wynne, Edward Price........Aberystwith.

Resolved—That the following, having passed their respective Examinations, be elected Associates of the Society:—

Major.

Brough, Henry James........Windsor.

Minor.

Appleby, Edward Joseph ....Brighton.
Bates, William ....Stevenage.
Blackwell, Frederick William Birmingham.
Constance, Herbert Edward ..London.
Cortis, Arthur Brownhill ....Worthing.
Dear, James Edward ....St. John's Wood.
Edwards, Thomas............Newport, Monm.
Evison, William ....Louth.
Green, Vittery ....London.
Greenish, Thomas Edward....London.
Haworth, Benjamin Henry....Manchester.
Houghton, Robert William ..Bermuda.
John, Jabez Arundel ....Tenby.
Jones, Matthew Henry ......London.
Langham, Henry John ......Diss.
Latham, Robert John ....Worksop.
Maitland, Alick..............London.
Williams, William Griffith....Abergele.

Modified.

Cox, John James Wilson ....Brighton.
Griffits, John Alonza ....Wantage.
Johnson, Robert Armstrong ..Newcastle-on-Tyne.
Probyn, Clifford ....Kennington.
Shemmonds, John ....Coventry.
Watson, Charles ....London.

It was resolved—That the Report and recommendations of the Library, Museum and Laboratory Committee be received; and the following books recommended for the Library were ordered to be purchased:—

Lyell's Principles of Geology.
Merrifield's Technical Arithmetic and Mensuration.
Wood's Notes on Heat, etc.
Darwin's Origin of Species.
Smith's Pharmaceutical Guide.
Frankland's Lecture Notes—Organic Chemistry.
Humboldt's Cosmos.
M'Culloch's Dictionary of Commerce and Commercial Navigation.
Annuaire Pharmaceutique.

The Committee presented the Annual Report of the Council, which, with alterations, was agreed to, and ordered to be issued with the Voting Papers for the election ensuing of Council and Auditors.

Resolved—That the Report and recommendations of the House Commitee be received and adopted.

The Report of the Finance Committee was received and adopted, and sundry payments ordered.

Resolved—That the Report and recommendations of the Parliamentary Committee be received and adopted.

The Report of the Provincial Educational Committee was read. It recommended the expenditure of more money on provincial education, and stated that in the opinion of the Committee, the applications for aid would have been more numerous had the conditions been less stringent and less fettered by details. It therefore recommended certain amendments in the regulations.

Mr. Williams suggested the question whether the proposed alterations would really widen the sphere of provincial pharmaceutical education.

Mr. Atherton said they would no doubt do so to some extent, but in his opinion the whole matter would have to be gone into systematically and on a broader basis by the new Council. He therefore doubted the advisability of doing a thing partially which would have to be re-considered so soon.

The President thought the new Council would be assisted in this matter by the recommendations of the Committee being adopted.

Mr. Shaw thought it most important that something like the principle of "payment for results" should be inaugurated in connection with this matter. In the case of Liverpool there had not been such a demand for pharmaceutical education as might have been expected, and the facts showed the necessity of some regulations which would ensure the funds of the Society being wisely expended. For the last twenty years every desirable means had been provided in Liverpool for giving a thorough systematic pharmaceutical education, lectures on Botany, Materia Medica, and Chemistry being delivered, but although there must be from three to four hundred apprentices and assistants in the town, these lectures had not been attended by more than half a dozen, while the Materia Medica lectures were attended by *two* only.

Mr. Hills asked if the masters had given their young men the opportunity of attending.

Mr. Shaw said he was simply speaking of the facts, not entering in any way into the cause or causes. He had heard that in other places masters had insisted on the time spent by their apprentices in attending lectures, etc., being made up at the end of the term. Individually he was prepared to vote for any amount being expended on the advancement of provincial education and was very much pleased with the action of the Northampton Association as stated at the last meeting. He hoped that by degrees it would become generally known by parents and guardians, that under the regulations which required every chemist to pass his examination before entering into business, it would be essential that ten or twenty guineas should be expended on lectures, etc., at the conclusion of a young man's apprenticeship. He thought on the whole the matter had better be left to the incoming Council, and suggested that it would be well if the balance sheets of the various provincial Societies were forwarded, so as to show that all was fair, and above board, and that it might be known who had done their duty and who had not.

Mr. Stoddart said that his experience at Bristol was quite at variance with that of Mr. Shaw at Liverpool. The Bristol Association had made no application for assistance, though he had been asked several times to do so; but he had always said they had better do all they could for themselves first, and then if absolutely necessary they could ask for assistance, and he was sure the Society would grant it. He believed every druggist in Bristol had joined their Association, which had now been in operation for two seasons, and had been very prosperous indeed. Last year there were classes in Chemistry, Botany and Materia Medica, the number of students at the commencement being 18, and the same at the conclusion of the session. He found that two of the young men had since passed their minor examination, although the last lecture was only given in February. This showed they ought to be rather circumspect in this matter, and see that people tried their best to help themselves before asking assistance.

Mr. Shaw said that Liverpool had not applied for assistance. He asked if Mr. Stoddart had not virtually applied the system of payment for results, by requiring a fee of 5*s*. only for the lectures (which he gave gratuitously) if the students attended regularly, whilst 10*s*. was exacted if they did not.

Mr. Stoddart said the fee was uniformly one guinea, which was devoted to the formation of a museum of materia medica. The 5*s*. subscription to which Mr. Shaw had referred was requisite to constitute a young man a member of the association.

Mr. SAVAGE thought the suggestions of the Committee were very admirable, and really met Mr. Shaw's views.

The Report of the Committee was then adopted.

Mr. SANDFORD suggested that a special resolution should be passed, embodying the proposed alterations in the regulations.

Mr. ATHERTON thought it would be useless to do so, as the Council were so soon going out of office.

Mr. SANDFORD thought it would be, at any rate, taking a step in the right direction. He saw no reason why a given amount should not be voted to a provincial association, and left to be expended as necessary. The regulation hitherto acted upon had stood greatly in the way of assisting provincial education, though the principle of granting aid had been fully established—first by a resolution at General Meeting, and afterwards by repeated resolutions at the Council. He would, therefore, move that the alterations recommended by the Committee be made in the code of rules marked "No. 1."

Mr. GROVES suggested that the motion which Mr. Frazer brought forward at the last meeting should be incorporated, so that all applications should come before the Council together and be decided at the same time.

Mr. FRAZER said he was still of opinion that money for this purpose should be voted upon some general principle, and he knew of none except the state of the balance sheet. He thought Mr. Shaw's idea of payment for results was really met by the proposed regulations. He always thought it a mistake not to give any assistance towards lectures, which it appeared to him were equally worthy of encouragment with the collection of books and specimens.

Mr. WILLIAMS thought the course of the discussion showed how difficult the question was, and that it had really better be deferred. If they adopted the resolutions, they had no guarantee they would be acted upon in the future. As Mr. Atherton had remarked, it was a large question, and must be dealt with on some great principle, and he hoped this would be done by the new Council.

Mr. HILLS agreed that the question had not been gone into sufficiently yet; but this was a step in the right direction, and he would therefore accept it for the present. He believed London members would be very liberal in the matter. For his part, he would at any time give half as much as the local Society itself raised.

Mr. BETTY said it was from no want of desire on the part of the Committee to enter into the question on a broad basis that they did not go further in the regulations proposed. They were simply put forward, and the Committee wished them to be accepted as an earnest and evidence of the good feeling of the Council towards advancing pharmaceutical education in the provinces. They would willingly have gone a step further, but it would have been impossible to go into the whole question at present, because they could not complete the work. The broad question had not been lost sight of, though the Committee had not been able to come to a decision upon it. Several plans had been proposed, and one was mentioned which he believed would some day have to be adopted, viz., that schools should be established in so many provincial centres—say 12 or 14,—where pharmaceutical education should be given, similar to what was done in the case of the medical schools. He also agreed with Mr. Frazer's suggestion that the balance-sheet, showing what was done with the funds voted, should be presented annually. He had mentioned a sum of £600, to be divided into 12, which would give £50 to each, and that, he thought, should be granted for one or two years; and even at the expiration of that time assistance might be given according to the results of the teaching. The schools must be established first, and the results paid for afterwards.

The PRESIDENT thought Mr. Betty was going rather further than the Report before them warranted.

Mr. BETTY said he was only giving the reasons why the Committee were not able to go into the general subject, though they were very desirous of treating it in a comprehensive manner.

The resolution was then put and carried.

(In order that the alterations may be fully understood, the Regulations as amended are printed at page 893, *the alterations being in italics.*)

Resolved—That the Report of the Conversazione Committee be received and adopted.

Mr. SMITH then drew the attention of the Council to a circular which had been sent round with regard to the forthcoming election, headed "Pharmaceutical Society of Great Britain," and, therefore, purporting to emanate from that Society. It appeared to him a very important matter, and, as he thought, unless some immediate steps were taken it would have the effect of vitiating the whole election. He thought those who had put it forward had subjected themselves to legal penalties.

Mr. GROVES was of the same opinion. He had not seen it before.

Mr. SMITH said it was important to stop such a matter at once, for no one could say on what occasion a similar thing might be done next.

After some further discussion, in which several members took part, the matter was referred to the Parliamentary Committee, with instructions upon it as the solicitor should advise, to take such steps that a meeting of the Committee be called immediately.

Mr. CARR drew the attention of the Council to a letter in a recent number of the Journal, by Mr. Scholefield, regarding the investment on the Benevolent Fund account. He suggested that if the amount invested in consols were turned into Metropolitan three and-a-half per cents., there would be an increase of income of upwards of £40 per annum, with perfect security.

48	27	21

Mr. CARR said as this was the last monthly meeting of that Council he begged leave to move a cordial vote of thanks to the President for the very able and courteous manner in which he had discharged the duties of his office during the past year.

Mr. SMITH seconded the motion, which was carried unanimously.

A similar vote of thanks was given to the Vice-President.

ERRATA.

Conditions for Making ard Receiving Grants and Loans in Aid of Provincial Schools of Pharmacy.

The alterations now agreed on by the Council are printed in italics.

1. Grants in aid of Provincial Education in Pharmacy shall be made for the *special* purposes of supplying materials for class-teaching, such as apparatus, specimens, diagrams, chemicals, class-books, etc., and also towards the formation of libraries, *or for the general purposes of advancing education where satisfactory evidence is given that the Association from which the application proceeds is really promoting that object and needs assistance.*

2. That application for such grants be made in writing to the Council on forms provided for the purpose, by local Associations of Chemists and Druggists, signed by the Secretary of the Association and by three resident Members of the Pharmaceutical Society.

3. That each application shall state the kind *and amount* of aid required.

The following portion of the original clause to be omitted, [and, where a money grant is applied for, shall indicate the sum intended to be applied to each specific purpose.]

4. That where a grant is made for the purpose of providing *materials for class teaching*, etc., the applicants *shall guarantee* their safe custody for a period of three years. The said materials to be *the loaned property of the Pharmaceutical Society for three years*, after the expiration of which they may be resumed by it, or otherwise disposed of. The Council may, in special cases, forego this guarantee where it deems it not desirable.

5. Applications for the use of apparatus from the "*loan collection*" of the Society may be made by local Associations of Chemists and Druggists, and grants made for periods of fourteen days, in accordance with the following rules:—

1. A list of the apparatus which the Society is prepared to lend, or which may be hereafter added to the collection, shall be published in the Journal, and printed for circulation in a separate form. Such lists may be obtained from the Secretary of the Pharmaceutical Society.

2. The apparatus shall only be lent to Associations of Chemists and Druggists, and applications for the loan thereof must be made in writing, on forms provided for the purpose, signed by the Secretary of the local Association, describing the articles required, and directed to the Secretary of the Pharmaceutical Society.

3. The Secretary of the Pharmaceutical Society shall refer any application so received to Dr. Redwood, who, with the assistance of the Curator, shall supply the same, subject to approval of the President or the Vice-President of the Society, and to the following conditions:—

A. No apparatus shall be lent for a longer period than fourteen days, unless a renewed application is made for it.

B. All apparatus so lent shall be at the risk of the borrowers, who shall defray the cost of any damage that may occur to it.

C. Packing cases and packing will be provided and paid for by the Pharmaceutical Society; but cost of carriage must be paid for by the borrowers.

D. A list of the apparatus lent to local Associations shall be sent to the Secretary applying for it, who shall sign and return it as a receipt for the apparatus when received.

6. Applications for aid to Libraries must be accompanied by particulars of the number of volumes already contained in such library, and the name of each book applied for, and its price specified.

7. The relative claim of any town to receive aid from the Society must be indicated by the earnestness and efficiency of local effort. A complete curriculum of chemistry, practical chemistry, materia medica, pharmacy and botany is the standard to be aimed at.

8. All applications to the Council for aid may be referred to a standing Committee appointed annually for this purpose. The recommendations of the Committee to be laid before the Council for action thereon.

To the Council of the Pharmaceutical Society of Great Britain.

Form of Application for Grants in Aid of Provincial Schools of Pharmacy.

Name and Address of Association applying for Grant . } ______________________

(In the following Divisions state the object or objects for which the Grant is required, and the amount it is desired to appropriate to any or each of the following purposes)—

A For providing apparatus, specimens, diagrams, etc. Specify the articles required, and the amount of grant requested . . } ______________________

B For providing books, etc. for library. State the particulars of the number of books already in the library of the Association, the titles and prices of the books it is now desired to purchase, and the amount of grant requested . . . . . } ______________________

C For any other object. State the purpose for which the grant is required, and the amount requested . . . . . } ______________________

D *For the general purposes of Pharmaceutical Education, give the balance-sheet of the Association for the preceding year, and the number of students availing themselves of the opportunities offered. Also state the reason for requiring aid from the Pharmaceutical Society* . . . . } ______________________

As the relative claim of any town to receive aid from the Society must be indicated by the earnestness and efficiency of local effort, state here any consideration which, in the opinion of the applicants, entitles them to a grant from the Society's funds . . . . } ______________________

PHARMACEUTICAL MEETING.

Wednesday, May 1st, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The following donations to the Library and Museum were announced, and the thanks of the Society were voted to the donors:—

Durham University Calendar: from the University,—Minutes of the Convention of Pharmaceutists and Druggists, 1851; Proceedings of the National Pharmaceutical Convention, 1852; Proceedings of the American Pharmaceutical Association, 1855, 1867, and 1871: from the American Pharmaceutical Association,—Bark of *Memecylon grandis*, the Ki-temboga or copper tree, of Java, from Ceylon; Bark of *Cerbera Odallam* of Ceylon; Essential Oil of *Chavica* (*Piper*) *betle;* Essential Oil of *Gaultheria punctata:* all presented by Dr. J. E. De Vrij,—Oil of *Eucalyptus globulus;* Oil of the pericarp of the Cashew-nut; Oil of Cashew, from the kernel; Eucalyptol, from *Eucalyptus globulus:* presented by Mr. G. Brownen,—Specimen of Crude Chloride of Potash, as imported from Saxony: presented by Messrs. Hodgkinson, Stead and Treacher, —A very fine specimen of one of the Vertebral Bones of the Whale: presented by Messrs. Hopkin and Williams.

Professor BENTLEY made some observations on the donations of Dr. De Vrij. He said he had understood that the bark of *Memecylon grandis* had been sent partly for analysis and partly because Dr. De Vrij had found it useful as an astringent. He thought it was very likely that it was so, because it belonged to a Natural Order, *Melastomaceæ*, many of the plants of which have a slight astringency. If there were any particular value to be derived from it, that would be shown when we get more particular information in connection with it. It was always a matter of great interest that such men as Dr. De Vrij should bring us specimens from different districts, because that was the only way to introduce new remedies into this country.

Mr. COLLINS said that the specimen of *Gaultheria punctata* was in illustration of Dr. De Vrij's article in the Journal. With regard to the bark of *Memecylon grandis*, Dr. De Vrij thought it might also be used in tanning. The native name, Ki-temboga, is given on account of the very characteristic copper colour of the bark.

Dr. TILDEN said that at the last meeting there was laid upon the table a specimen labelled "bisulphite of magnesia," and since then a paper had been written by Mr. Archbold, in which an account was given of the properties and composition of the salt, as well as details of its analysis. Dr. Tilden's attention had been directed to the subject, partly in consequence of the improbability, already pointed out by Mr. Carteighe, of the existence of such a compound, and partly, by what seemed to him, the singular and incoherent style in which the paper was written. He was always happy to welcome any new worker in the field of science, but he thought Mr. Archbold was not very familiar with the kind of investigation he had undertaken. Dr. Tilden had analysed the specimen which had been presented to the museum, and found it was no "bisulphite," but simply the ordinary sulphite of magnesia, containing six molecules of water of crystallization, and which would be found described in many of the text books. The formula given by Mr. Archbold was an impossible formula. That a solution of an acid sulphite of magnesium might exist, and that in certain cases it might be a useful remedy, he did not dispute, but the specimen before the meeting was certainly incorrectly named, and he thought it highly improbable that any such compound could be produced in the solid form.

Mr. WILLIAMS said that he had no special knowledge of bisulphite of magnesium in the crystallized form, and thought it would probably be very difficult to produce; with respect to the soluble bisulphites, especially those of potash and soda, the following test could be employed, to determine if they were bisulphites or simply sulphites,—it depended upon the fact that bisulphite of lime was soluble in water. A solution of chloride of calcium added to a solution of the bisulphite to be tested will produce no precipitate if the salt is perfect, but if a precipitate be produced (it may be sulphite or carbonate) the whole should be thrown on a filter, and the filtrate precipitated by lime-water, by which means the excess of sulphurous acid would be neutralized, and from the amount of sulphite thus produced, the percentage of bisulphite originally present in the sample could be easily calculated.

PHARMACY IN AUSTRIA.

[Mr. GREENISH then read a paper on "Pharmacy in Austria," which is printed at p. 881, and gave rise to the following discussion.]

Mr. BETTY said they ought to be very much obliged to Mr. Greenish for the very exhaustive and practical essay which he had written. He had, in common with every pharmacist, been very much pleased with the contrast existing between the practice of pharmacy in England and on the Continent. He thought it ought to act as a warning to English pharmacists, and lead them to watch very zealously, lest the independence which attaches to the national institutions and the spirit of an Englishman should be in any way compromised or destroyed by that petty and over-legislation which so prevailed in foreign States. He hoped the Government of this country would never be afforded any pretext for commencing it. It was too often thought that the making up of a prescription was a mere mechanical action requiring no skill, and especially was this the case in foreign countries, as was shown by the amount paid for the skill in making up a prescription in Austria. In the instance given by Mr. Greenish, two-thirds of the price was paid for the mechanical operation of dividing the powders and for the box and gold label. He was glad to see that German pharmacists were trying hard to get rid of that over-legislation which had proved so irksome to them.

Mr. GROVES said that, although it appeared that in Germany pharmacists were harassed by unnecessary legislation, nevertheless, on the whole, benefit resulted to them from it. One thing he observed was that all young men who entered their names were required to pass a preliminary examination in arts. He thought that would be about the best thing that could happen in this country. It was highly absurd that a pharmacist here was compelled to undertake certain examinations before he could open a shop and conduct a business, and yet immediately after that he might engage any one he liked for his subordinate, and pay him as little as he liked. He thought that in this the public health and safety were not considered, and that no one ought to be engaged who was not thoroughly qualified. Referring to the remark of Mr. Greenish, that the young men in Austria had two hours a day to themselves, he said that he thought every master ought to allow that amount of time, and also afford access to a laboratory and other apparatus. He could not help remarking the prevalence of the objection of pharmacists to laboratories. He much regretted it, and hoped that more would be established. He had himself conducted one for many years, and he intended to bring the subject forward in the Journal, and endeavour to show how one might be carried on at very small expense, and with very great profit.

The PRESIDENT said he should like to ask Mr. Greenish what time the apprentices commenced work, and at what time they ceased their ordinary labours; and what was the time of the day they got for study; and how many hours they were allowed for meals? for he thought that when they had been informed on these matters, probably young men present would be better satisfied with their position than they were now.

Mr. GREENISH said the assistants went to business very early indeed, usually about six o'clock, and the shops were kept open to a late hour. But the apprentices had generally two hours every evening for study, and the assistants two half-days every week for recreation. The apprentices and assistants were a greater number of hours in business than in this country. A pharmacist mentioned to him that though the apprentices had two hours given them every evening, there was the greatest difficulty in keeping them at study, for they would go to the *cafés*.

Mr. WILLIAMS said he could not say anything about the practice of pharmacy in Vienna, but he had seen something of it in the more country parts—in the Tyrol. His impression was that the pharmacists were in anything but an enviable position, especially compared with us here, and no one would wish to change places; and that was amply proved by the scale of charges allowed for a prescription. It could not be a very remunerative business, even where money goes a great way. As far as he could judge, they seemed to be in a very unsatisfactory position indeed. There appeared to be two classes of society, and only two—the nobility and gentry and the peasantry, and no intermediate class; and the chemists were really drawn from the lower class, and they were allowed to get a miserable living, and that was all. He might be wrong, for he could gather but little information except by what he saw, but such was his impression, and he thought their position was not at all of an enviable character.

Mr. HILLS said he could endorse what Mr. Williams had said, that English pharmacists are in an enviable position compared with pharmacists in other parts of the world. He would not deny that the hours were very long, but they had been much longer. In his time they had been very much curtailed, and they were still being curtailed, and it was to his younger friends that they all looked to uphold pharmacy in England. They must remember this: in pharmacy the position a man occupied would depend very much upon himself, whether he was an apprentice behind the counter or a shopman; a man could take almost any position he liked if he displayed intelligence and courtesy and gentlemanly conduct. It must not be forgotten that lately two or three of their body had received the honour of knighthood; but he would not be satisfied with that, for he hoped to see some of them baronets, and perhaps rise even higher still. It was to the students of the present day that he looked to place pharmacy in the position it ought to be. He thought he might be permitted to say that he believed he was the first associate of this Society, and when he first commenced, students had nothing like the privileges they have now. When he came to Oxford Street they only had one or two books, such as Thomson's 'Dispensatory,' Turner's 'Chemistry,' Hooper's 'Dictionary,' and Thomas's 'Practice of Physic.' At that time, with the help of Mr. Mackay, of Edinburgh, they formed a class among themselves, and they used to get what information they could during their meals and after nine or ten o'clock, after which time their class was held. If they had gone through all that, and yet pharmacy had attained its high position, he would tell his young friends present what they expected of them. Having gone so far themselves, now they expected a great deal more from those who were coming on the stage. Of course, in thus assisting in the progress of pharmacy in England, they had benefited themselves. It was for the present students to persevere, to work hard; and in working hard, they might depend upon it, success would crown their efforts, and they would find it to be the happiest time in their lives. When they were at work, let them work with all their might.

Mr. GREENISH said he endorsed Mr. Williams's remarks as regards pharmacy in the Tyrol, but he thought they would not apply to Austria generally. There the pharmacists were well off. The limitation of pharmacies on the Continent is such that a business becomes valuable; much more is paid for it because of this Government concession. There can be no opposition. A pharmacy returning a thousand a year would fetch several thousands of pounds there. There is a society now established in Berlin trying very hard to get freedom of trade. As regards social position, the pharmacist is a gentleman and can mix in any society.

Mr. WILLIAMS suggested that he had a private income as well.

Mr. GREENISH said he was not sure of that. But he must have been able to put his hand upon a good sum of money in order to have bought the pharmacy.

Mr. BETTY asked if any reasons could be given for the Government limiting the number of apothecaries' shops?

Mr. GREENISH replied that the great reason why the limitation was not done away with was because it was a Government concession; and if it were abolished and there were freedom of trade they would have to make compensation, which would involve the payment of an enormous sum of money. He also said that it was the feeling of a large number of people, many of whom, however, were out of business, that this over-legislation was very injurious to the interests of pharmacy generally, and he believed it was himself.

The PRESIDENT said he could well understand the comfortable position of pharmacists in Austria, from the fact of the number being so limited. He had no doubt if half the pharmacists in this country would emigrate or go to another world it would be a capital thing for those left behind. But when he looked at the scale of charges there for what we called skilled labour, he felt sure that our assistants would be greatly dissatisfied with that proportion of pay. One sentence in the paper he could not help smiling at, and that was that the master had to see that the intended apprentice wrote fluently and plainly. This was particularly necessary to prevent the patient being mislead. He remembered on the last occasion it was said that very often the medicine was given to the person who came for it wrapped up carelessly and not sealed, so that frequently, if it happened to be a wet day, by the time the messenger reached home it was impossible to tell what was written upon the label.

Mr. GROVES said that these men enjoyed tolerable incomes, notwithstanding the lowness of price; and he thought their position after all was to be envied.

Mr. HILLS said he could not agree with Mr. Groves that the pharmacists did not take a position in this country. He believed it was entirely their own fault if they did not. He did not care whether a man was in the shop or where he might be, if he conducted himself properly and straightforwardly, and showed intelligence and a love of his profession, he always took a position. It was true he might not get into the House of Lords; but, as his friend near him suggested, he could go into the House of Commons. He thought it was altogether a mistake to decry the position of pharmacy.

Mr. GROVES said that living in the country as he did he found that, with a certain class of people, it was customary to look down on pharmacists, though he admitted it was not so with others, and mentioned an amusing instance that had occurred in his own experience.

Mr. Betty, referring to the position of the future pharmacist, said that, in his opinion, very much would depend upon the education he received. If a sound preliminary education were secured, and this followed up by earnest and persevering study, he believed pharmacists might lay claim successfully to a very high position in society.

Mr. Walter Hills said that as to the position chemists took in Germany, it ought not to be forgotten that most of them made chemistry, botany, or some other scientific pursuit their particular hobby, and devoted themselves wholly to it, and this gave them a certain position; and being always at scientific meetings, and so forth, they mixed in the highest intellectual society, and thus were able to hold their own against everybody. As regards the position of assistants abroad, he thought they were not at all in an enviable position. In France, as far as he could judge, they were very badly off indeed. He thought that an English chemist in a pharmacy in Paris would get about double the salary that a man would get in one of the French pharmacies. It ought also to be remembered that Sundays abroad are much less free than they are in England. Most assistants here get at least one Sunday in two. The long hours, small pay, and bad lodgings provided in many cases, made their position a very unenviable one.

Mr. Greenish said he could confirm what the last speaker had said as to pharmacists abroad taking some particular subject, and instanced several men who had devoted special attention to different branches of the science.

The President said that the subject was now closed; but he would like to make one observation. According to the original proposition, it was intended to have another meeting on the 5th of June, but it had been suggested that it would be advancing rather too far into the summer, and, therefore, unless some special notice was given to the contrary, there would be no further meeting this season until October next.

A vote of thanks was then proposed by Mr. Williams, and carried with acclamation, to the President for his courtesy and kindness, and the ability with which he had presided at the evening meetings of the Society.

A vote of thanks was also given to Mr. Greenish for his able and interesting paper.

Provincial Transactions.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

The First Annual Meeting of this Association was held on March 20th, at its rooms, Royal Arcade, Newcastle; the President, Mr. Shaw, in the chair.

On rising, he reviewed at some length the benefit to be derived from such an association as their own. Besides the association being a source of improvement, it had also been the means of creating a more friendly feeling amongst the assistants and apprentices of Tyneside than had ever before existed. He felt happy that they had been so successful during this their first session, as the Secretary's report would show.

He then called upon Mr. Alfred Brady, the Secretary, to read his report:—

"A Meeting of Chemists' Assistants and Apprentices was called September 5th, 1871, to consider the desirability of forming an association, which ended in a Society being formed, and committee, etc., elected.

"On Thursday, September 21st, Mr. Shaw (the President) read the inaugural address in the Museum of the Natural History Society, after which the Secretary read a paper on Alchemy.

"On Thursday, October 5th, the first of the ordinary meetings was held in the rooms now held by the club, at which Mr. Melhuish read a paper upon the various Sennas of Commerce.

"Since then papers have been read on the following subjects:—

"Tobacco, by Mr. Anderson; Cell-formation, by Mr. Heslop; Opium, by Mr. Shaw; Gum Acacia, by Mr. Greenwell; Specific Gravities, by Mr. Brady; Chlorine, Bromine, etc., by Mr. Pittuck; Iron, by Mr. Charlton; Dispensing, by Mr. Welch; Mercury, by Mr. Marshall; Solution, by Mr. Spence; Water, by Mr. B. S. Proctor, (a lecture); Cod Liver Oil, by Mr. Foggon; Cinchona Barks, by Mr. Owen; Oxygen, by Mr. G. Proctor; Iron, by Mr. J. Aslin, (a lecture); Opium, by Mr. Shaw, (2nd paper.)

"The average number attending the above meetings was 23½.

"It seems to me needless to go into the various grievances that have been discussed at various times; all have, I think, been fairly settled, and the Society is now in full working order.

"The number of members now is altogether about 60.

"We have had, besides donations in the form of cash, the following articles presented to the Society:—

"A Materia Medica Cabinet, by Messrs. Crozier and Smith; do. do., by Messrs. Evans, Sons, and Co.; do. do., by Messrs. Southall, Son and Dymond; a handsome set of materia medica specimens, by Messrs. Hodgkinson and Co.; a case of various tobaccos, by Mr. Jones; a large number of specimen jars, by the York Glass Company; do. do., by Mr. Mather; do. do., bottles, by Messrs. Maw and Co.; a number of shelves, by Mr. J. Swan; the Pharmaceutical Journal weekly, from the Society; 'the Chemist and Druggist,' by Mr. B. S. Proctor; do., by Mr. Welch; set of labels and map, by Mr. Barber; a ballot-box, by Mr. Simpson. Besides the things above mentioned, a considerable number of books have been lent. So that altogether we have not come off very badly and have, if work is meant, ample means for any student to pursue his studies."

The report was unanimously received by the members. The treasurer's report was then read, which showed a balance of £10. 1s. 3d. in favour of the Society. On the motion of Mr. Shaw, seconded by Mr. Charlons the report was received.

The election of officers for the ensuing session then took place. There were nominated for the presidency Mr. W. Shaw and Mr. Alfred Brady.

Mr. Shaw declined to take office again on account of pressing business engagements, thereupon Mr. Brady was elected unanimously.

There being no opposition, the following gentlemen were elected to the various offices.

Vice-President, Mr. Simpson; *Secretary*, Mr. G. H. Proctor; *Treasurer*, Mr. G. T. Marshall; *Committee*, Messrs. Shaw, Bullus, Owen, Heslop and Welch.

This concluded the business of the evening. The meeting then adjourned.

At the meeting on April 25th, the minutes of the last meeting having been read and adopted, the President elect delivered his opening address, which was as follows:—

Gentlemen,—Before thanking you for the honour you have conferred upon me in making me your President, it may be well for me to take a retro as well as a prospective glance at our general proceedings. Our late President, Mr. Shaw, told us in his opening address that one of his reasons for wishing to form an association here was that he, as things then stood, knew no one out of his own shop who was connected with the trade, and with whom he could associate or spend the evenings after the business of the day was concluded. This object has, I think, been to a great extent obtained, inasmuch as a large number of young men from the different establishments in the town have met together for the sake of social intercourse,—some to read, some to examine and talk over the numerous specimens in our collections, and others to enjoy a quiet pipe or game of chess. But this is not the only thing that came before the minds of those chiefly concerned in commencing our club. The primary object was to give our younger members all the advantages possible, to enable them to get up knowledge sufficient to pass the now compulsory examinations of the Pharmaceutical Society. Few indeed are the chances that an apprentice, say in a small shop in an out-of-the-way part of the town, has, especially where the premises are not closed till eight or even nine o'clock—few I say are the chances for such an one to pass his examination with any credit. He goes home, or to his lodgings, as the case may be, tired and too sleepy to do any good work. Now, if he chose, he can come here, have a quiet hour with little or no interruption, and, as a rule, can have any question answered or theory explained, and go away having passed a comparatively satisfactory evening; and by the time he arrives at his journey's end he will feel refreshed, and look forward with pleasure to the next day's duties.

At our meetings which have been held on Thursday evenings, and which are devoted to the reading and discussion of papers, we have had a fair diversity of subjects. I should like to see more of our younger members come forward in these; for depend upon it there is nothing which fixes a subject so well on the mind as reading that subject up with the purpose of writing an essay upon it for the benefit of others. And you may take it for granted that no paper you can read, if it has taken any reasonable amount of time and care to prepare, can pass without giving some instruction to all its hearers. I should like to see more members come forward with lectures, such as Mr. Heslop delivered at the commencement of the session, for, though his was really an essay on the cell-formation of plants, it was a subject on which little or no discussion could follow, as what he stated were facts not to be argued, but taken as such. We are, I think, exceedingly fortunate in having a friend like Mr. B. S. Proctor, who is able and willing to lecture to us, as he has shown, and who takes such interest in all that concerns the good of the association. Our thanks can do little to repay him for time and trouble he has taken on our behalf, but we can by following profit by his advice, and endeavour to show him that we are gratified for the pains he has taken.

With regard to the classes formed in the latter portion of last half year, we made one mistake, in having too many of them. It was not to be expected that any members could possibly attend them all; if, instead of four, two were commenced per week, as well as the ordinary meeting held on Thursdays, there would, I think, be a chance of a fair attendance at every one. You must see that it is not right to expect a man to spend the time necessary to get up a lecture on any subject, more especially a series of such lectures, and to get together the specimens required for them, if after all, only two or three gentlemen come to hear him. For my part, I would rather have eight or nine really attentive students than twenty who did not seem to care about the information they received. But, where are the eight or nine? I have heard more than once of the class not being held, because only one or two came to it. Now, if these classes are to be a success, there must be more attenders; and I cannot help thinking that there must be a large number of assistants in the various chemists' shops in Newcastle and Gateshead who would, if they only knew it, derive a good deal of profit by attending such classes. I do not expect that it would be much good to start them again until the summer is over; but when winter evenings commence, that is at the beginning of next session, I hope we shall be able to set to work again with renewed vigour. But, though we may not have any lectures on botany, you must not forget that it is in the summer that the plants are to be collected for use and study. I would recommend every one to take every chance he has to gather and preserve by pressing every sort of wild flower he can lay hands on—I said flower, but I did not mean only the flower. The botanist takes stem, leaves, and as much root as is convenient or possible to obtain. I would not have him simply keep medicinal plants, though they always make a large and interesting collection, as there are numberless herbs growing in our hedges which, though they do not enter into our Pharmacopœia, yet have, in times gone by, been used in medicine, and many that are still used, though seldom.

All that a botanist requires is a tin case or vasculum, and a pair of boards with two good strong straps, and a few folds of blotting-paper; with these he is fully equipped for his work. Many a time when I have been taking a holiday have I longed for the pressing-boards which I had thought too much trouble to take when leaving home.

They are really of very little bother, and few things are more annoying than to find a plant which you do not know, and wish to preserve, without having the means at hand.

Having said so much with regard to the necessaries for pursuing the study of botany, it is only needful to say that, having got your plant, the first question is to find out by general characters the Natural Order to which it belongs, and after that its more minute or specific characters, to arrive at the determination of the species; it may seem difficult at first, but really a very superficial knowledge of the Natural Orders is enough to distinguish them. Many of them, such as Umbelliferæ, Compositæ and Cruciferæ, are told at a glance.

Mind, let not what I have just said as to superficial knowledge lead you to think that I consider that sufficient; the temptation to be content with surface-work is naturally too strong when certain examinations are prominently in view. No one can suppose that any permanent good can be derived from such study, or does he intentionally lay himself out for such a course of smattering. Intentions are always good at starting. A new broom sweeps clean; but it requires determined and sustained effort to resist the compromises between inclination and duty, which so soon present themselves. The enthusiasm and excitement attending a change of occupation will carry most young men through the first stage of student life, without much drain on the store of these good resolutions; but there then comes a period when the drudgery of learning seems far to outweigh the fruits of knowledge obtained, and then it is that those who began with fair promise seem to fall away. But then the force of habit, together with a natural curiosity and gradual acquirement of knowledge, engenders an increasing thirst for more. It is then that temptation is strongest to be content with superficial study, when the attendance at classes or lectures is apt to become a formal thing, accepted as a task, in the hope that just sufficient knowledge can be obtained for examination purposes. The listless attendance of lectures can be of no real value. It is a mistake to suppose that the most gifted professor can teach you except by showing you the way to learn, and placing before you faculties to be worked out by your own industry. The right acquirement of knowledge is an individual work that no man can perform for you. The condition in which the drudgery of the onset becomes a labour of love is attainable by any of you, and until it is obtained, scientific progress is hard and uncertain. By ardent study, sticking closely to it, you will soon derive a pleasure from it not to be obtained in any other way. Ever remembering the injunction of King Solomon, "Whatsoever thy hand findeth to do, do it with all thy might." To conclude, gentlemen, I sincerely and heartily thank you for the honour you have done me in placing me in the high station of President of this Association, and I trust that I shall never cease to regard this Association with increasing interest. We may at some future period have a North of England branch of the Pharmaceutical Society, and who knows but what we may be the original cause of such a proceeding. We are, through the help of our hard-working and indefatigable Secretary, Mr. George Proctor, I believe increasing our numbers, and if you will all join and work hand-in-hand, I feel certain we shall rise quickly to the position of one of the best—I mean most useful and well-working-Associations, in the kingdom.

NORWICH CHEMISTS' ASSISTANTS ASSOCIATION.

On Friday, 12th ult., the Winter Session of the above Association terminated, and with it, the weekly classes, with the exception of that for the Preliminary Examination, which will be continued until July next.

In spite of the offer of prizes at the beginning of the session, the attendance has been very limited; the few students, however, who have been regular have worked well, and, it is hoped, will show to advantage in the examinations which will be held.

Three prizes of books are to be awarded to those who obtain the highest number of marks in a *vivâ voce* examination on those subjects taught by the Association; the fourth, given by the Vice-President, for the best written answers to a chemistry paper.

For this last, Professor Attfield has kindly consented to award marks.

Lately the Council have largely increased the library, consequently there has been a much more extensive circulation than heretofore.

The museum has also been increased, principally by donations from some of the leading London wholesale firms.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Annual Business Meeting of this Association was held in the West Hall, Anderson's University, on the evening of Wednesday, 24th April last; Mr. Thomas Davison, President, presiding. There was a large attendance of members. The minutes of the last meeting having been read by the Secretary and approved of, Mr. J. J. Weir brought forward the motion of which he had given previous notice, anent the present unnecessary Sunday traffic. He supported his motion by a lengthened address; and after a good deal of discussion for and against, in which Messrs. Kinninmont, John Black, Brodie, Fairlie, the President, and others took part, the following motion was unanimously agreed to:—

"That this association views with sincere regret the widespread traffic in unnecessary articles on Sundays; and, having the honour and good of our profession at heart, we resolve to appoint a committee to draw up circulars, first, requesting employers connected with the drug business to discountenance the sale of such articles which do not necessarily come within the province of medicines; second, an address to the public, in the form of a card which could be placed prominently in the shop, where the attention of customers might be drawn to it, and thus induce them to desist from inquiring for such articles; and, third, to the various ministers throughout the city, asking their assistance, and that of their congregations, to curtail or put a stop altogether to the unnecessary traffic. Messrs. Davison, Kinninmont, and Weir to be the committee."

The Secretary, Mr. Fairlie, was then called upon, and read, as follows, the

Annual Report for Session 1871-2.

"The continued prosperity of your association is a great cause for congratulation. Many societies such as yours, long before they reach the age of your association, pine away and die through ill-health; but yours has gone on from strength unto strength, always growing in usefulness and influence as it grew in years.

"Session 1871-2 has been no exception. The membership consists of 38 employers, 50 assistants, and six apprentices, numbering 94 in all,—a smaller number, no doubt, than that of the year immediately preceding, but the new meeting-place being somewhat of a novelty last year, together with the small subscription, accounted in some degree for the great accession to the number of members last session. This year, however, that novelty has worn off, while the increased subscription, we are sorry to say, has prevented many from joining us, while some of those have found the attractions of the Assistants' Association and the agitation for early closing more in accordance with their wishes. We are convinced the late hour of meeting also prevents many from becoming members, and we earnestly hope that arrangements may be made next session which will enable us to meet at least an hour earlier than hitherto.

"The proceedings throughout the session just closed have been carried on with the usual spirit, the chief features being the opening address by Mr. E. C. C. Stanford, of the British Seaweed Company, and the address on 'Indian Poisons.' by Professor P. A. Simpson. The Association has also been indebted to Mr. M. H. Cochrane, F.C.S., Demonstrator in Anderson's University, for two very practical papers which were beautifully illustrated. To these gentlemen your Council would again tender their most sincere thanks.

"The other papers by members were more numerous this session than formerly; and several of these having found their way into some of the trade journals, proves, to some extent at least, that they were of no mean order.

"The discussions held throughout the year, though not so animated as in some previous years, were well sustained by the members generally, and were both interesting and instructive.

"The annual festival, which took the form of a supper this year, was quite a success in every way.

"The pharmaceutical botany class, conducted by Mr. Hennedy, and the chemistry class by Dr. Moffat, have been comparatively well attended throughout the year, but the experience of your Council in regard to these special classes has brought them to the conclusion, first, that a single course of lectures given once a week is not sufficient to prepare students for the various examinations to be passed in connection with pharmacy; and second, that in a city like Glasgow, where so many educational advantages exist at such reasonable terms, they are not altogether necessary.

"The late hours in many of the establishments throughout the city, is a very great hinderment to students taking advantage of these cheap evening classes; but your Council would recommend that all students should make such arrangements with their employers which would enable them to take advantage either of the morning or evening classes in the Andersonian University. It may be well to mention that the usual matriculation fee is not charged to pharmaceutical students, and it might be a recommendation for the Council elect to ascertain if students in pharmacy could not be allowed to attend the Andersonian classes on more advantageous terms even than the regular students. Our main grounds for this conclusion is the fact that only 18 members came forward this session to Dr. Moffat's chemistry class, and that a loss was incurred of about £6 to the Association; those who did take advantage of it, however, have derived considerable benefit, though, as stated above, the term was too short for all practical purposes. These and other reasons have prevented your Council from entering into any new arrangements for special classes.

"The number of failures in connection with some of the examinations of the Pharmaceutical Society has attracted considerable attention of late, more especially with regard to apprenticeship and provincial education; and we are glad to observe that the Council in London, principally through the exertions of Mr. Frazer, the Glasgow representative, have decided to reconsider the mode of giving aid to provincial associations. And your Council hope that before another year, some such proposal as that suggested by Mr. Frazer will be agreed upon, and that in future those societies throughout the country, such as yours, requiring aid, will have something tangible to look forward to each year, and not, as at present, an isolated and paltry sum which, hitherto, your Association has considered not worth asking for. It is certain, at all events, that provincial associations can do but little of themselves without the prospect of regular help from the Pharmaceutical Society, a body which at present is drawing very large sums from the very class who require their help.

"The question of prices, we observe, has again come up for consideration, and your Council express the hope that Glasgow, which has for so long been behind other towns in this respect, will soon be on a level with its compeers. A better opportunity certainly could not present itself than the present, when not only tradesmen of all grades are getting higher wages and shorter hours, but the present high price of many drugs and chemicals demand that something shall be done to remedy the anomalous state of things which has existed so long among us.

"Your Council are glad to record that the early-closing movement has at last resulted in something fruitful; and we earnestly hope that those still adhering to the late hours will be induced this summer to adopt the eight o'clock movement also. We would not be wanting in our duty, however, if we did not acknowledge that the present reduction of the hours, on the south side of the river especially, has been stimulated to a very great extent by the exertions of the Assistants' Association, a society which has sprung into existence chiefly for this purpose, though, we believe, they intend, after securing the short hours, to remain organized for mutual improvement. Your Council look upon this step of the young men as very promising for the future body of pharmacists. It is to hoped, however, that they will not only acknowledge gratefully what has already been done for them by this Association, but will go hand in hand with them in endeavouring to advance the educational status of the trade.

"Your Secretary has received regularly as published, the PHARMACEUTICAL JOURNAL, *Chicago Pharmacist*, and *Chemists and Druggists' Advocate*, all of which have been largely taken advantage of by members who have not other opportunities of perusing these journals.

"In conclusion, your Council trust that the earnestness and energy which has hitherto characterized the members of your association will continue; and as we hope ere long to have increased facilities for meetings and mutual intercourse, may we always have in view the advancement of pharmaceutical science; and as our business is one of a humane nature, may we, in our studies as well as in the pharmacy, do our utmost to alleviate the sufferings of our fellow men."

Mr. YOUNG, treasurer, was then called upon, who read the financial statement of which the following is an abstract:—

RECEIPTS.

	£	s.	d.
To Balance from last year	4	18	1½
,, Donation, W. and R. Hatrick and Co.	1	1	0
,, Do. Wm. Greig (New Apothecaries' Co.)	1	1	0
,, Do. Thomas Davison	1	2	0
,, 4 Donations at 10s. each	2	0	0

Audited and found correct.

(Signed) JOHN M'MILLAN, ROBT. T. DUN } *Auditors.*

Several motions where then brought forward, and referred to the Council for further consideration.

The election of officers, council, and auditors for the ensuing year was afterwards proceeded with, and the following were declared duly elected:—*President*, Mr. Thomas Davison; *Vice-President*, Mr. John Jaap; *Treasurer*, Mr. Wm. Young; *Secretary*, Mr. J. A. Clarke; *Council*, Messrs. Daniel Frazer, Alexander Kinninmont, Wm. Whyte, John Black (Rutherglen), John M'Millan, J. M. Fairlie, John Fenwick (Strathbungo), Robert Brodie, Archibald Paterson, Andrew Waddell, J. J. Weir and John Murdoch; *Auditors*, Messrs Robert T. Dun and Jas. L. MacMillan:

On the motion of the CHAIRMAN, seconded by Mr. A. W. RITCHIE, Messrs. Brodie and Fairlie were awarded a very hearty vote of thanks for their valuable services as vice-president and secretary to the Association during the last three years.

The meeting then separated.

THE NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Monthly Meeting of the above Association was held on Thursday, April 25th, in their rooms in College Street Mr. MASTERS, President, in the chair. The Secretary (Mr. DRUCE) read the minutes of last meeting, and announced that they had received during the month a grant of ten pounds from the Pharmaceutical Society, a Bunsen's burner from Mr. Dadford, book for prescriptions from Mr. Negus, and Lindley's 'Introduction to Botany' from Mr. Barry.

Mr. MASTERS said he should be only expressing the feeling of all the members when he said how deeply gratified they were at having received the grant from the Council, and how each would do all in his power to show that the confidence put in them had not been misplaced; the apparatus and books which they had thus been able to purchase would prove invaluable to them in their practical chemistry class, which he had no doubt would prove very successful. He was sorry that the reading of papers did not occur more frequently. Some little misunderstanding must exist, he thought, as to what was required in a paper; he would suggest that it should be made as terse as possible, either original or a digest from the best authorities. Alluding to the method of preparing certain tinctures, he thought that percolation was not the best mode of procedure, and suggested that maceration for seven days, with frequent agitation, would give much better results. He also very strongly objected to the tinctures being made up with spirit to a definite quantity, as he believed it impossible by so doing to produce tinctures of the same strength by different makers.

After a long and exhaustive discussion, the SECRETARY read a paper on "The Origin and Early History of Chemistry," in which, after touching upon its probable beginning, and the discoveries made by the Egyptians, Arabians, and Chinese, and its eventual introduction into Europe, proceeded to notice the chimeras those early philosophers indulged in, namely, the Philosopher's Stone, the Elixir of Life, and the Universal Solvent, and the time wasted in their unprofitable employment. He concluded by saying that if they copied the alchemists in their perseverance, they would possess a philosopher's stone which would transmute base ignorance into pure knowledge; and, though they had not the elixir of life, yet they might have a greater satisfaction in knowing they had not misused their talents, and helped not only themselves but their fellows.

The President said he hoped that the half-yearly meeting would be held on the 2nd of May, and proposed that the Principals be invited to attend.

THE BRADFORD CHEMISTS' ASSOCIATION.

The following circular has been issued by the Council of the Bradford Chemists' Association:—

"The Council of this Society feels it to be a matter for deep regret that the lectures it instituted about three years ago should be discontinued for want of support by those they were intended to benefit. The aim of the Society was to help the assistants and apprentices then in the town to pursue their home reading preparatory to the examinations that are now required of all.

"This has been so strongly felt, that it has been urged that a vigorous effort should be made to rekindle the slumbering interest of the young men in this matter, and to press upon their attention its importance. It is with this object that negotiations have been entered upon with Mr. Callaway, Secretary and Curator to the Philosophical Society, to deliver a course of ten or twelve Lectures on Elementary and Structural Botany, to the Associates of the Society, gratis, on payment of their annual subscription.

"The Council also wishes to say a word with regard to the object and purpose of these and all lectures; that they are not intended, and cannot do away with the necessity for personal study and effort; but by conveying in a clear and systematic manner, the leading principles of the subjects treated of, they will greatly facilitate the progress of students, by enabling them to understand many difficult matters, that would altogether bar their progress without such help; the ultimate object being to shorten and make easy the study necessary for passing any of the examinations of the Pharmaceutical Society.

"In conclusion, the Council find it impossible to make personal solicitations of each individual, but as the matter is one of personal interest to all, it is hoped that all will join the class, and forward their names to Mr. Harrison, Mr. Bell, or Mr. Rimmington at once, so that arrangements can be completed for commencing the first week in May.

"F. M. Rimmington, }
"F. Bell, } Committee."

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Monday, April 29th.

Juries Bill.

The second reading of the Juries Bill was deferred until Thursday, the 9th of May.

Public Health Bills.

The Committees on the Public Health Bill and the Public Health and Local Government Bills were deferred until Monday, the 6th of May.

Wednesday May 1st.

Adulteration of Food, Drugs, etc., Bill.

The Committee on the Adulteration of Food, Drugs. etc., Bill, was deferred till Wednesday, the 15th of May.

Correspondence.

Election of Council.

Sir,—I have received from the Chemists' Defence Association a circular setting forth the names of fourteen persons selected from the list of gentlemen nominated for the ensuing Council, as being the most fit for election. The issue of this circular under the heading, "Pharmaceutical Society of Great Britain," renders it incumbent on those who desire to to maintain the independence of individual members to protest most strenuously against this usurpation of the name of the Pharmaceutical Society of Great Britain.

There are doubtless good names on this list, but when the Council absolutely needs an increase in the number of London members, why should such men as Messrs. Savory, Stacey, Malden, Burdon, Carr, Starkie, and Wade be handicapped?

Fair Play.

Sir,—I did not intend to trespass upon your space, or in any way advocate my claim to a seat in the Council, but as an opinion exists that if each candidate publicly expressed his sentiments, it would enable voters to judge for themselves who best represented their views, and so obviate the necessity for any individual or party to select for them, or to attempt to bias, or blindly lead in favour of one or the other; therefore, with your permission, I will briefly state the reasons that induced me to accept the honour, having been nominated for the Council.

For many years before the passing of the Pharmacy Act, it is well known I took a prominent part in all that related to the bringing about the incorporation of the trade, exemption from jury service, and associating outsiders with pharmaceutists in friendly co-operation. After three years I find little has been done by the Society and its Council, to enable it to say it faithfully represents the trade, or more than one section; and yet it was constituted the governing body over all. I am convinced that the true policy of the Society, both for financial reasons and political strength, is to secure the support of that large body of outsiders, who, for some cause to be ascertained, have as yet refrained from giving their confidence. My desire is, and will be, if elected, to make the Society honoured and approved by all chemists and druggists, to offer such inducements as will bring members and friends to the succour of the Institution, to cause its educational means to be as useful and well applied in provincial schools as at the Metropolitan Academy, to give confidence in the distribution of its funds to those who now lack it, by having none to represent them or their donations.

I desire the Council to become thoroughly representative, strong in the support of all classes, a power capable of resisting medical influence or dictation, able to combat restrictive legislation that does not emanate from itself, for its own security.

I would uphold the right of every man to carry on his business as heretofore, without penalties, or what is still more odious, Government surveillance, whether it be dispensing or general trade. My proceedings last year in opposition to the compulsory regulations, and the amendment which settled the question at the annual meeting, are substantial evidence of my aversion to that unnecessary and objectionable measure.

I regret finding myself antagonistic to many efficient and excellent men who will contest the election, but who in my opinion too strongly represent high-class pharmacy, to the prejudice and indifference of the middle-class and ordinary druggist; but if the propositions I have advanced are agreed to by any members, and who believe with me that the Society is competent to become of greater utility, if worked on a wider and more liberal basis, then I respectfully solicit their votes and interest.

April 29th, 1872. John Wade.

J. Levers.—Your letter has been handed to the Secretary. We are requested to say that it was a printer's error.

We are compelled from want of room to defer the publication of several communications and answers to correspondents.

Communications, Letters, etc., have been received from Mr. A. Weavers, Dr. C. R. A. Wright, Mr. Wilkinson, Mr. Bell, Mr. Pocklington, Mr. Druce, Mr. Cooper, Mr. Stott, Mr. Proctor, Mr. Hayland, Mr. Ellwood, Mr. Richardson, "Chemist and Druggist."

OBSERVATIONS ON TESTS FOR QUININE AND MORPHINE.*

BY PROFESSOR FLÜCKIGER.

The most characteristic test for ascertaining the presence of quinine is the formation of the splendid green compound called *Thalleiochine*, which is produced if solutions of the alkaloid or its salts are mixed with chlorine-water and then a drop of ammonia added.

It is known by Pelletier's researches that some other alkaloids are also altered by the above treatment, yet without assuming the same colorations. Morphia, for instance, shows a red hue, very quickly turning dark brown.

I was induced by a lamentable poisoning case to examine the behaviour of the two alkaloids when mixed. The first question was to ascertain the smallest quantity of *quinine* which, in solution, displays the green colour. If one part of quinine is dissolved in 4000 parts of acidulated water and then about $\frac{1}{10}$ of the volume of the liquid of chlorine-water and a drop of ammonia added, a green zone will be readily formed if the liquids are cautiously placed in a flask without shaking. If the solution of quinine contain no more than $\frac{1}{5000}$, the green zone may still be obtained, but in more diluted solutions the success becomes more and more uncertain. From a practical point of view we may state that $\frac{1}{5000}$ of the alkaloid is the smallest quantity whose presence can thus be discovered with certainty. Kerner (1870) has succeeded with $\frac{1}{20000}$, but I was not able to corroborate this statement.

As to morphine, its solutions assume a yellow hue if chlorine is added, whereas chlorine does not at all alter the colourless solutions of quinine. The dark brown coloration of *morphine* in solution, to which chlorine-water and ammonia have been added, is no longer produced if less than $\frac{1}{1000}$ of morphine is present.

From these observations it may be foreseen what must happen if a mixture of salts of both those alkaloids be tested by chlorine and ammonia. The green colour, thalleiochine (thalleioquine), will appear notwithstanding the morphine if the amount of the latter is less than $\frac{1}{1000}$ of the solution. But the test for quinine fails if there be more than $\frac{1}{1000}$ of morphine present, even when the quinine is in considerable quantity. The green colour of the thalleioquine is enveloped by the dark dingy-brown colour due to the salt of morphine.

In a specimen of quinine containing morphine, or *vice versâ*, the presence of either of them can be shown as one pleases by means of chlorine and ammonia. In the comparatively concentrated solution the brown colour of morphine will make its appearance, whereas thalleiochine results as soon as the quantity of the solvent much exceeds the proportion of 1000 parts to one of morphine.

This is an illustration of the importance of not relying upon one test alone. In the fatal case alluded to, the presence of quinine happened to be ascertained, but morphine was overlooked. There was certainly no reason for presuming the presence of the latter, but one drop of nitric acid poured on the supposed hydrochlorate of quinine would have pointed out the presence of morphine, and spared the lives of two women.

I was curious to know the effect of bromine instead of chlorine in the above tests. The salts of morphine are apparently not altered by bromine and ammonia, but salts of quinine are more intensely coloured by the latter process. The thalleioquine is then indeed produced in solutions which contain only $\frac{1}{20000}$ of quinine. Yet the behaviour of bromine displays some striking differences. Chlorine alone, as already stated, causes no immediate alteration of somewhat diluted solutions of quinine, whereas they become turbid on addition of bromine as long as there is about $\frac{1}{2500}$ or more of quinine present. Now the precipitate which is produced by bromine in the solution of quinine does *not* turn green if a little ammonia is subsequently added, or, at least, the thalleioquine thus obtained is rather greyish. But in more dilute solutions of quinine, bromine acts more readily than chlorine. An excess of bromine is to be carefully avoided. This is easily performed if the vapour of bromine, not the liquid bromine itself, is allowed to fall down on the surface of the solutions of quinine; their superficial layer only must be saturated with bromine by gently moving the liquid. Then a drop of ammonia will produce the green or somewhat bluish zone, which is much more persistent than that due to chlorine.

Consequently, for demonstration of the test under notice, chlorine is to be used in comparatively concentrated solutions. In solutions containing so little quinine (less than $\frac{1}{2500}$), that it is no longer precipitated by vapour of bromine, the thalleioquine test succeeds much better with bromine, and goes much further, as shown above.

A well-known test for morphine is iodic acid, which is decomposed by the alkaloid, and forms a beautiful violet solution with bisulphide of carbon or chloroform. This test succeeds with solutions containing no more then $\frac{1}{10000}$ of morphine.

* Abstract of a paper contained in the 'Neues Jahrbuch für Pharmacie,' April, 1872, p. 136.

EMULSIONS.

BY R. ROTHER.

A perfect emulsion is a homogeneous liquid, more or less fluid, in which an oily substance, in an extreme state of mechanical division, is permanently suspended. The requisite ingredients of which an emulsion is composed are, primarily, an oily substance which constitutes the medicinal agent to be administered, then a mucilaginous or viscid body, by means of which the oil is divided and suspended, and finally an aqueous liquid, which, rendering the action of the second component available, also serves as the diluent and vehicle.

Emulsions may be classified as of two kinds, according to their origin, namely natural and artificial, —the first being the result of organic action, and the second, as the name implies, the work of art.

Natural emulsions are, firstly, milk and the yolk of eggs; secondly, the gum resinous juices of many plants, of which familiar examples are myrrh, ammonia and assafœtida; and, thirdly, numerous oleaginous seeds, familiar examples are the almond, flax and hemp seeds. The natural emulsions are all perfect, however much they may at first differ in physical appearance. The apparent difference is caused by a predominance or deficiency of water. The seeds finely triturated and gradually mixed with water, the gum-resins somewhat similarly treated, and the yolk simply diluted with water, will then all assume the physical characteristics of milk.

A perfect artificial emulsion is physically identical with the natural,—that is, as far as the extinction of the oil is concerned,—and this peculiarity is, in fact, the distinctive feature of an emulsion.

The preparation of a correct emulsion has been rightly judged as one of the most difficult tasks of the dispenser,—so much so, that a successful issue of the operation was attributed more to the dexterous skill of the manipulator than to the application of any particular method. However, as a successful result is not always assured, even in the aptest hands, it scarcely admits of a doubt that most of the manipulations now in use for the production of emulsions are utter failures—failures so far as to preclude the probability of an invariably definite result, not to say but that chance would frequently likewise lead to the same. The desideratum, therefore, consists in a process which, under certain necessary conditions, will always yield a perfect emulsion. To arrive at this, it is, firstly, required to examine the methods at present in use, and, secondly, necessary to inquire into the conditions most favourable for the production of an emulsion, and the principles upon which its formation rests. The following processes are such as came under the writer's observation:—

Firstly, the most inefficient of all methods was one strongly suggested in the *Druggists' Circular* a number of years ago, which consisted in shaking the oil, gum and water in a bottle until the emulsion was formed; it did produce a sort of mixture, but not what pharmaceutists usually accept as an emulsion. The shaking process is admirable for effecting solutions, but not so effective as the mortar and pestle for mechanical combinations.

The second process required that sugar, gum and oil be all rubbed together in a mortar, and then water be gradually added in small portions, with constant trituration. By chance a good emulsion would occasionally result in this manner, but mostly a large proportion of water would be absorbed, and the mixture still be too thick to pour. After a short time the peculiarly slimy mixture would suddenly resolve itself into a curdy or granular-appearing liquid having considerable fluidity. The same phenomenon occurs if a moderately increased quantity of water is added at once to the slimy combination, and then slowly stirred. After this relapse, the mixture could occasionally be doctored into a passable combination, by introducing more gum and triturating violently. But, in either case, most of the oil would rapidly separate on standing. It was supposed in this instance that the sugar greatly aided the process, but in the writer's experience sugar is really detrimental to the formation of emulsions. This process, among all the rest, is the most fatal, as in case of failure the loss of both time and material is incurred. The operation is more successful, however, if the sugar be added to the mixed oil and gum in the condition of syrup, and then followed by water.

By a third process, devised by Overbeck, given in a note to the U.S. Dispensatory, and also recommended by Mohr in his 'Pharmaceutical Technics,' a definite quantity of oil, gum and water, in proportions adjusted according to the nature of the oil that is employed, is all rubbed up at once in a mortar, and, when the proper union has taken place, more water is gradually added. This method is quite good, and yields very few failures where the oil does not exceed 2 fluid ounces, but with 4 fluid ounces of oil in one quantity the process becomes precarious.

A fourth method is given in the U.S. Dispensatory. According to it the gum is first mixed with water, in the same proportion as it exists in the officinal mucilage of the Pharmacopœia, the oil then added, mixed and diluted with the prescribed amount of water. In this case the oil is usually added in a thin but continuous stream with rapid stirring. This process is nearly as good as the preceding one, but often the emulsion is not as perfect as it should be.

These operations have mostly reference to the fixed oils and balsams, and are not equally applicable to the volatile oils, which, as a class, are much more difficult to emulsify. Experience demonstrates that the thicker and more viscid the oil the easier it is emulsified. The volatile oils, owing to their great mobility, are the most difficult to overcome. Castor oil and oil of turpentine are typical of these opposite extremes.

Thus it becomes evident from the disconnection and dissimilarity of these methods, that the true principle upon which the process of emulsification depends, has been either entirely unknown or completely disregarded. A perfect emulsion is characterized by its dazzling whiteness, its uniformity, and the property which admits of its dilution to even an extraordinary extent without destroying it appearance or identity. The incipient or complete emulsion, in its most concentrated form, from the moment of its generation, is unmistakably distinguished by its whiteness, and the peculiar tenacity which causes the pestle, when moved through it, to give the characteristic crackling sound of the emulsion; when these indications evince themselves the success of the operation is assured.

Now, the writer observed that by following Overbeck's method, and using a broad mortar, if the trituration be confined to a narrow space for a moment until perfect emulsification had taken place, even in a small portion of the material, and then gradually bringing the rest of it within this centre, a perfect emulsion was invariably attained. Applying this manner of manipulation in the process of the U.S. Dispensatory, that is, instead of pouring the oil upon the mucilage in a continuous stream, adding only a small portion at first; this, with the large proportion of mucilage, never fails to emulsify. The remainder of the oil is then added in small quantities at a time, and each perfectly emulsified before introducing the next. Finally, the perfect emulsion is diluted to the required measure. The writer now further observed that when the proportion of oil was great, in comparison to the mucilage, a time would arrive during the addition of the oil when this ceased to merge with the emulsion; in no instance, however, was the previously-formed emulsion ever disintegrated or deranged. Therefore, it was assumed that the inaction originated in a deficiency of water, consequently this addition was made, and complete emulsification again and immediately resulted. The addition of oil was then continued, occasionally adding water, until the original volume of mucilage had lost its comparative individuality in the overwhelming proportion of the oil, and still the process of emulsification progressed. The emulsion, during any period of the operation, could be diluted with water to any desirable volume without decomposition. This principle was now applied to oil of turpentine, assumed to be the most refractory in the category of oils.

Two fluid drachms of officinal mucilage of acacia was placed into a broad, conveniently-sized mortar, and diluted with one fluid drachm of water. Half a fluid drachm of oil of turpentine was then added, and the whole triturated a few moments until the oil was emulsified. One and half drachms of oil was then added, in half-drachm portions, emulsifying each before adding the next: this was followed by one drachm of water. Five fluid drachms of oil was now introduced in the same manner as before, and again followed by half a drachm of water. After this three drachms of oil were again incorporated as above, and still the emulsion retained its perfect appearance, and ever ready to extinguish quantities of oil to an almost unlimited extent. However, this was not required, and therefore the incorporation of oil was here discontinued, and the emulsion diluted with water.

Upon these deductions, the following theory is established :—A concentrated, perfect emulsion is in itself the most rapid and efficient emulsifier, and possesses the property of emulsifying oil to an almost unlimited extent.

This theory is expressed in the following rule of the emulsion :—

Introduce the emulsifier into a broad, conveniently-sized mortar; this may be already a perfect emulsion, as the yolk of eggs, but if it is gum this must be in the form of mucilage, either thick or thin, according to the nature of the oil. Now pour in a small quantity of oil, and triturate this with the mucilage until a perfect emulsion has formed, then add the rest of the oil in small portions at a time, and not until the previous addition has been perfectly emulsified, adding small quantities of water at intervals, as the indications may require. Finally, when all the oil has been incorporated, gradually add the prescribed volume of diluent. When both a fixed and volatile oil are prescribed in an emulsion, the fixed oil must be emulsified first before the addition of the other.—*The Pharmacist.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Sodii Chloridum, $NaCl$.—Chloride of sodium is found in greater or less quantity in the waters of all springs and rivers, and abundantly in sea-water. In the massive crystalline form, as "rock salt," it also occurs in beds of vast extent and considerable thickness, which are generally supposed to have been formed by the gradual drying up of inland seas.

It is from this source that all the table salt of commerce is obtained. Bay salt is produced from sea-water. Common salt is the chief source of other sodium compounds.

[§ It imparts a yellow colour to flame. The solution is not precipitated by perchloride of platinum, but gives with nitrate of silver a white precipitate ($AgCl$) soluble in ammonia, but insoluble in nitric acid.]

Common salt never consists of perfectly pure chloride of sodium, but contains small quantities of chloride of magnesium and of sulphate of sodium. The presence of the former explains the slightly deliquescent character of ordinary salt, and its action in discolouring silver spoons left in contact with it.

Spiritus Ætheris Nitrosi.—A solution of ethylic nitrite with aldehyd, and frequently other substances, in rectified spirit.

When a mixture of alcohol and nitric acid is submitted to distillation, no *nitrate* of ethyl is obtained as might, at first sight, be expected; but when the acid becomes sufficiently concentrated, a reaction sets in, in which part of the alcohol is oxidized and part converted into nitrite of ethyl.

$$\underset{\text{Alcohol}}{C_2H_5HO} + \underset{\text{Nitric acid}}{HNO_2O} + \underset{\text{Alcohol.}}{C_2H_6O} =$$
$$\underset{\text{Ethyl Nitrite}}{C_2H_5NO_2} + \underset{\text{Water}}{H_2O} + \underset{\text{Aldehyd}}{C_2H_4O} + \underset{\text{Water.}}{H_2O.}$$

The aldehyd, which is the principal product of the oxidation of the alcohol, distils over with the ether, accompanied by traces of acetic acid, and often of other bodies.

The process of the B. P. was devised with the view of obtaining a more uniform product by moderating and regulating the action of the nitric acid. Pharmaceutically speaking it is an admirable process, though it does not yield nitrous ether in a state even approaching purity.

A solution of nitric and sulphuric acids in rectified spirit is distilled from a retort containing copper turnings. At a temperature of about 175°–178° F. the liquid becomes covered by a head of froth, and the liquid distils rapidly for some time till, at a certain point, the froth somewhat suddenly subsides; more nitric acid is then added and the process resumed.

The copper was originally employed with the idea that it would, with the aid of the sulphuric acid, reduce the nitric to nitrous acid,—

$$\underset{\text{Nitric Acid}}{HNO_2O} + \underset{\text{Sulphuric Acid.}}{H_2SO_4} + Cu =$$
$$\underset{\text{Nitrous Acid}}{HNO_2} + \underset{\text{Water}}{H_2O} + \underset{\text{Sulphate of Copper.'}}{CuSO_4}$$

and that the latter would react in a simple manner upon the alcohol. Thus

$$\underset{\text{Nitrous Acid}}{HNO_2} + \underset{\text{Alcohol.}}{C_2H_5HO} =$$
$$\underset{\text{Nitrite of Ethyl Or Nitrous Ether.}}{C_2H_5NO_2} + \underset{\text{Water.}}{H_2O}$$

This occurs, however, only to a limited extent, and consequently the resulting spirit still contains nearly as much aldehyd as the old-fashioned spirit of nitre.

The aldehyd may be recognized by warming the spirit with an equal volume of liquor potassæ. A peculiar yellow soapy-smelling, resinoid compound, characteristic of aldehyd, is deposited on cooling. It cannot, however, be made to reduce silver in the form of a mirror, as is the case with aqueous solutions.

When any solution of nitrous ether is heated in a sealed tube with strong ammonia, nitrogen gas is evolved and alcohol generated.

$$\underset{\text{Nitrite of Ethyl}}{C_2H_5NO_2} + \underset{\text{Ammonia}}{NH_3} =$$
$$\underset{\text{Alcohol}}{C_2H_5HO} + \underset{\text{Nitrogen}}{N_2} + \underset{\text{Water.}}{H_2O}$$

The Sp. Æth. Nitr. of the Pharmacopœia is represented as containing ten per cent. of ether, of which two per cent. separates on agitation with saturated solution of chloride of calcium. Whether so much as eight per cent. remains unseparated is, however, very doubtful. Experiments on this point are wanted.

[§ It effervesces feebly or not at all when shaken with a little bicarbonate of soda. When agitated with solution of sulphate of iron and a few drops of sulphuric acid, it becomes deep olive-brown or black.]

The acidity is generally due to acetic acid, but in old specimens it is much increased in consequence of decomposition resulting in the formation of oxalic, formic, glycolic and glyoxylic acids, and doubtless other bodies. Acid spirit of nitre may thus be regarded as containing nascent nitrous acid, and, therefore, when mixed with iodide of potassium it frequently liberates iodine. This may be prevented by previously shaking it up with a few crystals of bicarbonate of potash.

(*To be continued.*)

THE SO-CALLED AFRICAN SAFFRON.

BY JOHN R. JACKSON, A.L.S.

(*Curator of the Museums, Kew.*)

From the description of the so-called African Saffron by Professor Maisch at p. 824 of the Journal, there seems no doubt but that the flowers are those of *Lyperia crocea*, Eckl., a scrophulariaceous plant of South Africa, small quantities of which have been imported into this country from time to time, chiefly for use as a dye. The following description of the plant and its uses is given by Dr. Pappe in his 'Floræ Capensis Medicæ Prodromus":—

"A little branchy shrub. Leaves very small, wedge shaped, fasciculate, obtuse, entire, smooth. Peduncles elongated, axillary. Flowers sub-racemose, yellow. Tube of the corolla much longer than the calyx. This bush deserves notice as a drug; and in all probability will, before long, become an article of colonial export. It grows abundantly in some parts of the Eastern districts, whence it has found its way into the dispensary. The flowers, which are called *Geele bloemetjes*, closely resemble saffron in smell and taste; they possess similar medical properties, and as an antispasmodic, anodyne and stimulant, ought to rank with the *Crocus sativus*. Here, they have as yet been only used with success in the convulsions of children, but they deserve a more general trial. On account of the fine orange colour which they impart, they are in daily request among the Mohammedans, who use them for the purpose of dyeing their handkerchiefs. This drug has been observed to be sometimes adulterated by the admixture of other plants of the same genus which are less efficacious."

About thirty species are recorded of the genus, all natives of the Cape Colony, and the flowers are mostly yellow or purple, always turning black in drying.

THE NATURAL HISTORY AND COMMERCE OF SPONGES.

BY JOHN GIBSON.*

(*Concluded from* p. 867.)

The sponges of English commerce are of two kinds, Turkish and West Indian. The Turkish sponge is found throughout the Mediterranean, but it is principally obtained from the eastern extremity of that sea, where, especially in the Grecian Archipelago, the islands of Cyprus and Crete, and the shores of the Levant, the fisheries of sponge take the place of the coral fisheries on the Italian coast. Along the coasts of Tunis, Barbary and Algiers an inferior kind, of a large-holed texture, known as the 'horse' sponge, is obtained. Sponges are found at greatly varying depths, but it is observed that those brought up from comparatively shallow water are usually of coarser quality; and that to obtain the soft, delicate ones, it is often necessary to descend to a depth of thirty fathoms. Aristotle observed this fact and tried to account for it. He says, "In general, those which grow in deep and still water are the softest, for the wind and waves harden sponges as they do other things that grow, and check their growth." Whether this be the true explanation or not, certain it is that our finest sponges are all brought up from a depth of at least eight fathoms. They are obtained by diving, an art to which the inhabitants of the Grecian isles and the surrounding coasts are specially trained from their earliest years, and dexterity in which is considered one of the first qualifications in a husband, while, in some places, it seems at one time, to have been considered a scarcely less important female accomplishment. Pomet, in his 'Complete History of Drugs,' says "The greatest part of the sponges that are sold come from the Mediterranean, and there is a certain island of Asia that furnishes us with a very large quantity of sponges. This isle is called Icarus or Nicarus, where the young men are not allowed to marry till they can show that they can gather sponges from the bottom of the sea; and for this reason when any one would marry his daughter, a number of young fellows are stripped and jump into the sea, and he that can stay longest in the water, and gather the most sponges, marries the maid."

These Icarian fathers evidently put little value on being over "head and ears in love," unless it be accompanied by a fair development of the power to remain over head and ears in water.

In his 'Voyages and Travels in the Levant,' Hasselquist tells of a somewhat similar custom, though rather differently applied. He says, "Himia is a little and almost unknown island, directly opposite Rhodes; we saw it in the morning on our right hand. It is worth notice, on account of the singular method the Greeks—the inhabitants of the island—have to get their living. In the bottom of the sea, the common sponge (*Spongia officinalis*) is found in abundance, and more than in any other place in the Mediterranean. The inhabitants make it a trade to fish up this sponge, by which they get a living far from contemptible, as their goods are always wanted by the Turks, who use an incredible number of sponges at their bathings and washings. A girl in this island is not permitted by her relations to marry before she has brought up a certain quantity of sponges, and before she can give a proof of her agility by taking them up from a certain depth." At the present time the Ottoman sponge fishery alone employs from four to five thousand men, who form the crews of about six hundred boats. On reaching the scene of operations, the diver finds his way to the bottom, taking with him a piece of stone of a triangular shape, with a hole drilled in one of its corners, through which a cord is passed connecting him with the boat. Having reached the growing sponges, he tears them off with his hands, sometimes

* Read at a Meeting of the North British Branch of the Pharmaceutical Society, April 18, 1872.

making use of a knife, and puts them under his arm; he then pulls the cord by which the signal is given to his companions to haul him up. Practice enables these sponge divers to stay under the water for a considerable time, in some instances as long as two minutes, although the average time of submersion is not more than eighty seconds.

Another mode of obtaining the sponge is by means of a pronged instrument. This is the plan adopted by the Greeks in the Morea, and also by those engaged in the sponge fisheries of the West Indies and coast of Florida, but the sponges thus obtained are generally torn, and sell at a low price. On removing the sponge from the water the gelatinous matter, which is of a brownish-yellow colour, and of a decidedly fishy odour, begins to run freely from it; it is necessary, however, to hasten this process in order to prevent the evil effects of putrefaction. For this purpose the sponge gatherers dig round, shallow holes in the sand along the shore filled with water, in these the living sponges are placed, and then trampled upon until their canals are entirely free of the gelatinous protoplasm, and nothing remains but the keratose skeleton known as the sponge of commerce, together with a certain quantity of sand taken in at the pores during this process, and which is got rid of afterwards. Of the two principal kinds of sponges brought into the English market, namely, the Mediterranean and the West Indian, the former are the most highly valued; and of these the sponges found in Turkish waters, and especially those along the coast of Crete, fetch the highest price in the market. They are known as Smyrna or Turkey or Greek sponges, and may generally be distinguished by their cup-like shape. They grow in masses from the size of a man's fist to that of his head, and as compared with the 'horse' sponge of the Barbary coast, or the huge species found in the West Indies and known as the 'Bahama' sponge, they are much closer and softer in texture, and less liable to tear. They appear to be somewhat rapid in their growth, as it has been noticed that a period of two years usually suffices to renew the crop of sponges on spots that had been laid almost bare by the sponge divers.

The importance of this branch of industry appears from the quantity of sponges which are annually imported by Great Britain alone. The total import for 1869 amounted to 1,221,000 lb. of sponge, valued at £157,000, of which from 200,000 lb. to 300,000 lb. came from the ports of the Mediterranean, and the remainder from the West Indies and the north Atlantic ports.

Although the term 'sponge' is usually associated in our minds with the commercial article, there are many other forms totally unlike, but which are as much entitled to the name as are those on our toilette table. Of these our own country possesses many species, none of which, however, have either the softness or the elasticity which gives its main value to the sponge of commerce. Dr. Bowerbank, who has written a valuable monograph on the British sponges, divides the class into three orders. The *Calcarea*, or those in which limy matter predominates; the *Silicea*, or those in which silica or flint forms the chief ingredient, and this order includes most of our British sponges; the third division is the *Keratose*, or those in which a horny substance known as *keratose*, forms either the entire skeleton or the greater part of it, and it is to this order that the sponges of commerce belong.

Among British sponges the following may be noticed:—The fresh-water sponge—*Spongilla fluviatilis*, which abounds in our rivers and canals. It is of a green colour when growing in situations exposed to the sun's rays, and of a dirty brown when otherwise situated. It is a curious fact that its green colour is owing to the presence in it of chlorophyll, the substance to which the leaves of plants owe their colour. The *Halichondria punicea*, found coating many of the rocks along our coasts. In this sponge the oscula are very distinctly seen, forming, as they do, the summits of little tubular eminences. A section of this, placed in a drop of water, under the microscope, shows jets of the most beautiful and varied colours issuing from the oscula like molten lava from the crater of a volcano. The several species of *Cliona* are remarkable for their habit of boring into the shells of mollusks, and thus causing the creature inside to form layer after layer of shell in order to keep back the would-be intruder.

Of foreign non-economic sponges, by far the most wonderful is the 'Venus' Flower Basket,'—*Euplectella Aspergillum*—certainly one of Nature's loveliest works. It consists of a tubular body about one foot in length, and from one to two inches in diameter, composed of a beautifully interlaced network of siliceous spicules, with its base enclosed in a thick tuft of siliceous glass-like threads, and its upper extremity closed by a curious piece of siliceous basket work. It is found in the Philippine Islands, where it is known as the *Regadera* or 'Watering-pot,' and is still supposed by the inhabitants to be the workmanship of a crab, from the fact that one and sometimes two crab-like crustaceans are generally found shut up in the hollow of the sponge. The lid-like covering at the upper extremity of the Euplectella is the portion of the skeleton last formed, so that the crab must make the sponge its habitation while it is open at the one end, and thereafter must remain a prisoner for life, dependent for its subsistence upon any food that may gain entrance through the network of its prison. These sponges are found at a depth of about 130 fathoms on a mud bank three miles from the coast of one of the Philippine Islands, where they are dredged for by the natives. When taken out of the water, they are of a dirty yellowish colour, but by washing in fresh water and exposure to the bleaching influence of the atmosphere they become a pure white, the condition in which they are usually brought to this country. The first entire specimen—that described by Owen in 1841, and now in the British Museum—was sold for £30, but of late years they have become more plentiful, and in 1867 were selling at between £3 and £4. Another sponge, found in Japanese waters and known as the 'glass rope," is somewhat allied to the *Euplectella*. It was first described as a vegetable production under the name of the 'glass plant;' subsequently Prof. Ehrenberg and others regarded it as an artificial production with which the Japanese sought to impose upon the credulity of the "Western Barbarian," but now it is recognized as the type of the genus *Hyalonema* of sponges.

We are all acquainted with the many uses, both in domestic economy and surgical operations, to which sponge is applied, and for which its power of absorbing liquids and of retaining them until forced out by compression, combined with its delicious softness, peculiarly adapts it. Formerly sponges were burned, and when reduced to a powder used as a remedy for scrofula, but any virtue it possessed was entirely owing to the presence of iodine and bromine, substances which are now obtained in larger quantities from other sources.

Sponges of all kinds are rich in nitrogen, containing about 16 per cent. of it, and where they abound in sufficient quantities on our coasts might be profitably manufactured into a valuable manure. One species—*Spongia tomentosa*—found on the coasts of England and North America, raises blisters when rubbed on the skin, a power which can be intensified by previously drying it in an oven. These are some of the uses to which man has, or might apply the sponge; but what, it may be asked, is its use in the economy of nature? It does not appear to constitute the food of any other class of animals; and though various mollusks and other creatures may habitually dwell in the network of certain of its species, yet, as Dr. Johnston remarks, "these are too trivial offices for so large and widely spread a family;" and the same writer thinks that "probably the power which its members possess of reducing to a solid condition the horn, the flint and the lime of the waters they live in, is what constitutes their importance among rival entities, and gives them a certain influence over the phases of this ever-changing globe — an influence not to be underrated when we take into account their vast numbers and universal diffusion; their size in more genial seas; and, above all, their unceasing operation in the waters, continued from age to age without a moment's intermission." And this view, especially as regards the aggregation of silex or flint, seems fully borne out by geological evidence. The large flint nodules found in the English chalk, and from which all the flint we have is derived, are supposed to be fossilized siliceous sponges whose presence in those ancient seas induced the deposit of silex around them; and thus it is that in very many flints we find a piece of fossil sponge in the centre, as a sort of nucleus for the surrounding layer of silex. It does, however, seem strange that to one of nature's softest productions we should owe one of its hardest, that the sponge of the past should be the flint of the present.

ON THE AMOUNT OF MOISTURE CONTAINED IN AIR-DRY DRUGS.

BY GEO. W. KENNEDY.

How many pharmacists would believe it if informed that the drugs which they are daily handling contain from 10 to 18 per cent. of moisture, which they lose in drying? I myself could scarcely credit it when my first experiments were made, and thought I might have lost some of the drug between the repeated weighings, but repetition of the experiments always confirmed the results previously obtained. Even the powders, which are supposed to be dry or very nearly so, lose in some cases from 8 to 10 per cent. of moisture.

I have experimented with a large number of drugs, sufficient, I believe, to give the pharmacist a true idea of the amount of moisture contained in them, and the results show conclusively that such pharmaceutical preparations like syrups, tinctures, fluid extracts, etc., must be much weaker when prepared from merely air-dry material than when made from anhydrous drugs.

The process of drying was conducted in a common cooking-stove oven, at a temperature of about 120° Fahrenheit, to which the drug was exposed until it ceased losing any more weight. By being exposed to a low but continuous heat, the loss in volatile oil may probably be greater than when the drug is dried at an elevated heat, but its normal amount is very small in most of the drugs experimented with, so that the deduction of the volatile oil expelled in drying would alter the figures below but little.

The dried drugs were placed in a room for two weeks and then re-weighed, the increase of weight representing the amount of moisture reabsorbed in that time. While these experiments were made the weather was cold and dry, and this circumstance doubtless accounts for the smaller percentage absorbed again, while in a few cases the loss of volatile oil may explain a portion of the deficiency.

The following tables show the loss sustained by the drugs mentioned, and the gain in weight of the dried articles under the circumstances mentioned above:—

	Loss.	Gain.	Yield by re-absorption.
1. Roots, Rhizomes, etc.			
Lappa	16·25	83·75	10·40

Amer. Journ. Pharm.

THE CALABAR BEAN.*

BY DR. L. VINCENT.

In a sojourn of nearly two years at the Gaboon, during which time he had opportunities of studying the numerous substances possessing medical properties produced in that part of equatorial Africa, Dr. Vincent's attention

* Journ. Pharm. et de Chimie [4], vol. xv. p. 109.

was particularly directed to the Calabar bean. It is used in that country, together with several other toxic agents, such as the *Icaza m'boundu*, the *Inee*, the *Alchiuse*, etc., by the tribes still plunged in barbarism and fetichism, for the compounding of their ordeal drinks. From a memoir giving the result of his inquiries we are enabled to glean the following particulars:—

The first specimens of this drug were sent to Europe by English missionaries from Old Calabar, where the natives called it "*éséré*." About ten years afterwards its botanical position was assigned by Professor Balfour, and at nearly the same time Dr. Fraser, of Edinburgh, while studying its physiological properties, discovered the remarkable property it possesses of contracting the pupil of the eye. In 1866 it was found in the French possessions in the Gaboon, not far from the banks of the rivers Como and Rhamboë. It is also found in abundance on the banks of the Ogo-wai; and as the physostigma prefers marshy and humid soils, it is probable that it occurs on the borders of all the rivers flowing into the Atlantic, from Old Calabar on the north to Cape Lopez on the south.

The Calabar bean is the seed of the *Physostigma venenosum* (Balf.), which has been placed by Balfour in the *Leguminosæ*, sub-tribe *Euphaseolæ*, the only tribe of the *Leguminosæ* that contains poisonous plants.

It is a perennial woody climber, attaining sometimes a height of from forty to fifty feet. It twines from right to left round the neighbouring trees, and in spite of any obstacles that may temporarily prevent its progress in this direction, it will after a time resume its course. The leaves are alternate, trifoliate, the middle leaflet ovate, very acute at the tip, regular at the base, stipulate, the lateral leaflets unsymmetrical. There are also two short stipules at the base of the general petiole. The flowers are disposed in clusters, and rose-coloured, with magnificent purple veins. The calyx is unequally five-toothed; the corolla papilionaceous with vexillary æstivation; stamens ten, perigynous and disposed in two fascicles, one consisting of nine stamens, and the other of one vexillary stamen; anthers bilobed, introrse, and dehiscing by two longitudinal slits. The ovary is stipitate and surrounded by a very long style, bearing a globular stigma, the surface of which is slightly hairy and covered with conical papillæ. Immediately below the stigma, on the convex part of the style, is a prominence having the shape of a falcate crest, which Professor Balfour appears to have looked upon as empty and vesicular, and therefore named the genus "*Physostigma*." The author, however, asserts that this prominence is full, and cannot be said in any way to justify the designation. The fruit is a pod $4\frac{1}{4}$ inches to 6 inches long, attenuated at both ends, a little compressed at the sides, bluish in colour; the valves are thickish, striated and rugose on their external surface, and smooth on their internal face, which presents in the intervals between the seeds a sort of whitish cellular tissue. Each pod contains two or three seeds, most commonly two. The seeds, which are the active part of the plant, for neither the leaves nor the stems are poisonous, are oblong, convex, and slightly reniform, a character which is more marked in the beans proceeding from Ogo-wai than in those collected in the neighbourhood of the Como and Rhamboë. They are from one to one and a quarter inches long, and about two thirds of an inch broad. The hilum, which surrounds nearly half the circumference of the bean, has the appearance of a long cicatrice, bounded by a slightly projecting line; is reddish and divided into two equal parts by a furrow that runs its entire length. The external tegument is testaceous, rather rough, and of a chocolate brown colour. In the interior is found a large fleshy embryo, with conical radicle accumbent to the cotyledons, which are ellipsoidal, hard, white, plano, convex, perfectly joined to each other at first, afterwards retracting, and leaving between them an empty space that constitutes a kind of central cavity.

Chemical analysis and microscopical examination have shown that the nucleus is formed of loose cellular tissue, containing large granules of amylaceous matter. These starch grains are oval or reniform, or sometimes assume the form of parallelograms with rounded angles; the margin is sometimes toothed. The spermoderm contains several colouring matters, which have recently been studied by M. Grassi, who thinks they might be utilized in the dyeing of silk. The active principle of the bean is the alkaloid discovered in 1864 by Jobert and Hesse, which has been variously designated physostigmine, calabarine, and eserine, from the name *ésérė* given to the plant by the Cameroons. It is amorphous, brownish-yellow, nearly insoluble in cold water, rather soluble in ammonia, carbonate of soda, ether, benzine, and alcohol. Its solutions in acids are generally deep red, but sometimes intensely blue.

The plant is also called by the Gaboonese *n'Chogo*, and by the Fans, *d'Itounda*. By the last-mentioned people the bruised seeds are made up into an ointment with palm oil, or some other excipient, and used to rid their bodies from the parasites with which they are covered.

TINCTURA OPII.

BY ALLEN SHRYOCK.

Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by $12\frac{8}{10}$ minims of the tincture, according to the U. S. formula; but a minute quantity of morphia has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed should indicate. To determine this difference, though slight, would be of interest.

Powdered opium was analysed, and found to yield $13\frac{21}{100}$ per cent. of morphia, giving 3171 grains in 50 troy ounces; this quantity being converted into 40 pints of tinctura opii, U. S. P., the dregs of the same were analysed, and found to contain 13 grains of morphia, upon which data we may readily calculate the loss as represented by morphia. Assuming the amount of morphia contained in the powdered opium to be represented nominally by 100 per cent., the amount of morphia retained in the dregs (13 grs.) will be represented by ·40996, or approximately $\frac{2}{5}$ of one per cent. Therefore $12\frac{8}{10}$ minims of tincture of opium in strength equals one grain of powdered opium less $\frac{2}{5}$ per cent., or $\frac{996}{1000}$ gr., and one grain of powdered opium in morphia strength equals $12\frac{85}{100}$ minims.

With this slight difference, however, $12\frac{8}{10}$ minims of the tincture may even represent more than one grain of powdered opium in therapeutic action, though lacking slightly in strength, from the fact of its being in a more diffusible state.

$\frac{66}{100}$ of the opium used was taken up by the menstrum, and each fluid ounce of the tincture contained 4·93 grains of morphia.

The residues left in making galenical preparations are always more or less charged with traces of the active principles. The proper menstrua and mode of preparing them presents a wide and interesting field for investigation.—*Amer. Journ. Pharm.*

TEST FOR ARSENIC IN SULPHURIC ACID.

The presence of arsenic in concentrated sulphuric acid may be detected by cautiously adding drop by drop from 2 to 3 c.c. to a solution of a little stannous chloride in from 4 to 6 c.c. of hydrochloric acid of sp. gr. 1·12, the liquid being gently agitated after each addition. If arsenic be present a yellow colouration changing to brown is produced; if not, the solution remains clear. This test is said to answer if the 500,000th part of arsenious acid be present.—*Dingl. Polyt. Journ.*

THE PROPOSED DINNER AT THE CRYSTAL PALACE.

With the view of affording the members of the Pharmaceutical Society, and old pupils of the School of Pharmacy, who may come to London to attend the Annual Meeting on the 15th May, an opportunity of meeting their fellow-members in the metropolis and other friends, a Public Dinner will take place at the Crystal Palace on Tuesday, the 14th of May, at six P.M.

The PRESIDENT in the chair.

STEWARDS.

Allchin, A., London.	Howden, R., London.
Atherton, J., Nottingham.	Linford, J., London.
Attfield, Professor, London.	Mackay, John, Edinburgh.
Barron, F., London.	Mackey, J. B. London.
Betty, S. C., London.	Martindale, W., London.
Bird, Aug., London.	McCulloch, F., London.
Bottle, Alex., Dover.	Malden, W. W., London.
Bremridge, Elias, London.	Paul, Dr., London.
Barnes, J. B., London.	Preston, Alfred, London.
Bentley, Professor, London.	Redwood, Professor, London.
Brown, W. S., Manchester.	Robbins, John, London.

Grenadier Guards' Band under the direction of Mr. Dan Godfrey.

Gentlemen willing to act as stewards will oblige by forwarding their names to the Hon. Secretary. Dinner tickets, including wine, one guinea each.

In order to make the necessary arrangements and prevent discomfort, members and *their friends* desirous of being present are requested to apply *at once* for tickets, enclosing a P. O. O. for the amount, to Mr. BREMRIDGE, 17, Bloomsbury Square, W.C., or the Hon. Sec., MICHAEL CARTEIGHE, 172, New Bond Street, London, W.

DILUTION OF GLYCERINE.

In a paper read by Mr. J. P. Remington, before the American Pharmaceutical Association, he called attention to the rise of temperature that occurs when concentrated glycerine is diluted with water, to which circumstance probably were due the irritating properties sometimes attributed to glycerine. He found that upon mixing together equal parts of glycerine, sp. gr. 1·254, and water at a temperature of 77° F., there was an immediate rise of 10° F. One part of water to four parts of glycerine caused a rise of 7° F.; so that when concentrated glycerine is applied to a chapped or ulcerated surface, it absorbs moisture from the skin, and sometimes gives rise to a burning sensation. If a small quantity of water be added to the glycerine before it is applied, this effect is very much mitigated. Professor Parrish bore testimony to the irritating effects sometimes produced by undiluted glycerine, especially in preparations for the eye. He said that he had met with cases where the pharmacist had been charged by the physician with introducing an irritating substance, such as sulphuric acid, for the purpose of dissolving the alkaloid, the fact being that the irritation originated with the glycerine employed.

PRECAUTIONS AGAINST ACCIDENTAL POISONING IN HER MAJESTY'S NAVY.

The following circular, dated 2nd April, 1872, has been issued by the Admiralty to all commanders-in-chief, captains, commanding officers, and medical officers of Her Majesty's ships and vessels, officers in charge of home and foreign hospitals, marine infirmaries (artillery and infantry), medical depôts and surgeries, and governors of Her Majesty's naval prisons:—

1. My Lords Commissioners of the Admiralty are pleased to direct that the following precautions against accidental poisoning be strictly observed on board Her Majesty's ships, and in all naval medical establishments at home and abroad.

2. All medicines or medicinal compounds of a poisonous nature kept in medicine chests or dispensaries are to be put up in bottles or jars of a dark blue colour only, and to bear labels of a yellow colour, having the word 'Poison' printed in bold letters over the name of the medicine.

3. All medicines or medicinal compounds of a harmless nature kept in the chests or in dispensaries are to be put up in bottles of white or pale green glass, or in jars of white ware, and to be distinguished by labels of a green colour.

4. All medicines labelled 'Poison' are to be kept under lock and key, and apart from the others, in the dispensaries ashore and afloat and in the medical stores of hospitals and depôts.

5. All medicines of a poisonous nature, whether for internal or external use, supplied to patients in the wards of hospitals or sick berths of ships are to be labelled with the yellow 'Poison' labels, and put into ribbed or fluted bottles of a dark blue colour only.

In order that this arrangement may be efficiently carried out, all ships and vessels are henceforth to be supplied with double the present numbers of blank yellow poison labels allowed by Scale B; and the stocks of 8-oz. and 4-oz. dark blue ribbed bottles allowed by Scale A are to be increased as follows:—To nine of each in the No. 1 chests, six of each in the No. 2 chests, and four of each in the No. 3 chests.

To gun-boats and coast-guard cruisers on the special scale, 24 blank yellow poison labels and four 4-oz. dark blue ribbed bottles are henceforth to be supplied with the medicine chests for dispensing purposes.

6. Medicines of a harmless character supplied to patients in hospitals or sick berths are to be labelled with green labels and dispensed in bottles of pale green or white glass only.

To ships and vessels double the present numbers of blank green labels allowed by Scale B are henceforth to be supplied; but no addition is at present to be made to the number of white or pale green bottles allowed by Scale A.

To gun-boats and coast-guard cruizers on the special scale, 24 green blank labels are henceforth to be supplied with the medicine chests; but the number of white or pale green 6-oz. E bottles is to be reduced from six to four.

7. No white labels, or labels of any other colours than yellow or green, as specified above, are to be used for medicine bottles or for dispensing; and no other kinds or colours of bottles and jars than those herein named are, under any circumstances, to be used for the purposes specified.

8. These regulations are to be carried into effect at once in all medical establishments, and on board Her Majesty's ships commissioned after this date. On board those ships and vessels now in commission at home or abroad they are to be adopted as soon as practicable, the necessary supplies of bottles and labels being obtainable on demand from the nearest naval medical depôt.

By Command of their Lordships,

VERNON LUSHINGTON.

The Pharmaceutical Journal.

SATURDAY, MAY 11, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL MEETING, THE ANNIVERSARY DINNER AND THE CONVERSAZIONE.

THE coming week promises to be a busy one for the Pharmaceutical Society of Great Britain, since among the "May meetings" which in London are far more characteristic of the month than the weather that is proverbially associated with its name, three gatherings of special interest to the pharmaceutical body are to take place. First, in order of date, there will be the Dinner at the Crystal Palace on Tuesday, which promises to be a success that will be very gratifying to the feelings of those gentlemen who have promoted it. The list of stewards that they were able to publish last week was eminently a representative one, containing as it did the names of a large majority of the gentlemen constituting the present Council, and of those nominated for the coming election, besides many others which are "household words" amongst us. But this week the list is, if possible, strengthened by the response of several other gentlemen, equally well known and respected. We hope that these favourable auguries may be so far realized as to justify us in the prophetic liberty we have taken of calling it an anniversary dinner.

Ushered in by the Dinner and to be followed by the Conversazione, as though it were intended to drown every possibility of an unpleasant reminiscence, the Annual Meeting will be held at twelve on Wednesday. The Council, following last year's precedent, have forwarded to each member a copy of the Report to be presented at that meeting. Considering the many topics dealt with in this Report, it would be vain to speculate as to the points which will chiefly occupy attention; but it cannot be too strongly pointed out that the annual meeting presents the most legitimate and best opportunity for the discussion of questions of interest to the Trade.

On Wednesday evening the President and Council will receive the guests of the Society at a Conversazione at South Kensington. The pleasant memories connected with past meetings of the kind require only a passing allusion. The band of the Grenadier Guards, under the direction of Mr. DAN GODFREY, will perform a selection of music for the benefit of the promenaders, and an effective glee company will be found in the Lecture Theatre. An ample supply of programmes of the music will be provided gratuitously, and one will be furnished to every visitor upon entering the Museum.

Of course the Annual Meeting can only be attended by those connected with the Society as members and associates in business. But with regard to the other meetings, their catholicity will be best shown by saying that they are equally open to all members of the Trade. All who may wish to attend either the Conversazione or the Dinner will be welcome, and they will be gladly supplied with tickets for the first by Mr. BREMRIDGE, 17, Bloomsbury Square; for the latter by any of the Stewards, Mr. CARTEIGHE, the Honorary Secretary, or Mr. BREMRIDGE.

STATISTICS OF ACCIDENTAL POISONING.

IT has long been the practice in this Journal to report the particulars of any case of poisoning that may from time to time occur, so far as the Society's local secretaries and other friendly correspondents in the provinces are kind enough to furnish the information; and it may be assumed that in this way our pages afford a tolerably ample record of such cases which would be of service in showing the extent to which poisoning is a result of ignorance, carelessness, or mischance on the part of those who sell or dispense drugs of dangerous potency.

Though participating in the hope we believe to be very general, that the disturbing subject of poison regulations may not again be raised, it has been thought desirable to collect together in a tabular form the principle details of all the cases that have been reported in this Journal since the passing of the Pharmacy Act, July 31, 1868, where an alleged negligence or mistake in dispensing or selling drugs has been the subject of a legal enquiry. The time chosen for a starting point appears to be a very natural one, as marking a great change in the conditions under which pharmacy is practised in this country. The list has not been drawn up with the object of favouring any particular opinions, but simply to furnish in a compact and readily available form what we believe to be the best information obtainable upon a point where hitherto speculation has to a great extent done duty for certainty.

As to the source from which the table has been compiled, it may be safely said, without asserting that this Journal records every inquiry into cases of supposed poisoning which takes place throughout the kingdom, that very few escape notice, and certainly none of importance do.

The arrangement of the matter has been carried out so as to appear to the eye in a clear and direct manner. The last column will be found to contain any explanation that has seemed necessary, together

CASES OF DEATH

Date.	Locality.	Reference to Report in Pharm. Journal.	Alleged Cause.	Mistakes in Dispensing.	
				Druggists.	Surgeons, Hospitals and Dispensaries.
1868. August 21	Stratford	x. 181	Baryta	. . . . . .	. . . . . .
—	Manchester	x. 325	Laudanum	. . . . . .	Bottle not sufficiently labelled

OR INJURY.

Mistakes in Sale.		Remarks.
Druggists.	Surgeons, Hospitals and Dispensaries.	
. . . . . .	. . . . . .	Verdict—"Died from effects of baryta accidently sold by Mrs. Hills for flowers of sulphur." Jury thought Mrs. Hills not fit person to keep druggist's shop.
. . . . . .	. . . . . .	Jury censured dispenser for giving out medicines unaccompanied by written directions as to quantity.
. . . . . .	. . . . . .	Open verdict; coroner complaining that while restrictions were placed on sale of strychnia, vermin killers were sold indiscriminately.
. . . . . .	. . . . . .	Suicide by vermin killer containing strychnia.
. . . . . .	. . . . . .	Verdict—Accidental Death.
. . . . . .	. . . . . .	Verdict—"Died from carbolic acid and oi administered in mistake."
. . . . . .	. . . . . .	First day of proprietor in shop. Verdict — "Misadventure," accompanied by a censure for manner in which the poisons were kept.
. . . . . .	. . . . . .	Verdict—Poisoning by misadventure.
. . . . . .	. . . . . .	Druggist censured by jury for want of care.
. . . . . .	. . . . . .	Censure for carelessness.
Sold for Godfrey's Cordial	. . . . . .	Proper bottle broken. Druggist took wrong bottle by mistake; both labelled "poison."
. . . . . .	. . . . . .	Surgeon not aware that crystalline strychnia was in his surgery. Bottle not labelled. Censured by the Jury.
? Sold for Sedlitz Powder	. . . . . .	Verdict for defendant (the druggist).
? Liq. Potassæ instead of Cinnamon Water	. . . . . .	Action against druggist. Verdict, £10 damages.
. . . . . .	. . . . . .	Verdict—"Death accelerated by Godfrey's Cordial." Mother reprimanded.
. . . . . .	. . . . . .	Drunk in mistake for spirit, although labelled "poison."
Sold by a child . .	. . . . . .	Censure of chemist for allowing child to vend poisons.
. . . . . .	. . . . . .	Child died in twelve hours after swallowing some.
. . . . . .	. . . . . .	*Chemist censured by magistrate for sale without witness or previous knowledge of prisoner.*
. . . . . .	. . . . . .	Action for damages. Verdict, £16.
. . . . . .	. . . . . .	Witness censured for signing poison-book without knowing deceased.
. . . . . .	. . . . . .	
. . . . . .	. . . . . .	Verdict—"Misadventure."
. . . . . .	. . . . . .	Over dose taken. Druggist committed for trial on charge of "manslaughter." Mother confessed she had not followed directions.
. . . . . .	. . . . . .	Taken in mistake for a cordial. Verdict—"Accidental death." Surgeon censured for not labelling "poison."
. . . . . .	. . . . . .	Child died. Verdict not recorded.
. . . . . .	Sold for Rochelle Salt.	Action. Damages, one farthing.
. . . . . .	. . . . . .	Verdict—"Over dose of opium through accidental causes."
. . . . . .	. . . . . .	Supplied by an "unqualified practitioner." Verdict—"Accidental death."
. . . . . .	. . . . . .	Surgeon and assistant censured by the jury.
. . . . . .	. . . . . .	Defence—Read "sal" instead of "sol."—Acquitted.
Oxalic Acid labelled "Citrate of Magnesia"	. . . . . .	Fined £5.
. . . . . .	. . . . . .	*Druggist censured by coroner for not registering sale.*
. . . . . .	. . . . . .	Attempted suicide. *Druggist censured by coroner for not registering sale.*
. . . . . .	. . . . . .	*Coroner wished to censure chemist, although the bottle was labelled "poison."* The Jury refused.
. . . . . .	. . . . . .	*Coroner said Syrup Poppies should be labelled "poison."*
. . . . . .	. . . . . .	*Coroner censured druggist for not entering the sale, and jury said a young man twenty years of age was too young to be trusted with poisons.*
. . . . . .	. . . . . .	Verdict,—Death from a narcotic.
. . . . . .	. . . . . .	Attempted poisoning. Supplied at open surgery by person not sober.
. . . . . .	. . . . . .	Attempt to compromise for £20. Action—result not reported.
. . . . . .	. . . . . .	Verdict—"Accidental death."
Sold for Rochelle Salt	. . . . . .	Verdict—"Culpable homicide." Two months' imprisonment.
. . . . . .	. . . . . .	*Fined 2s. 6d. for not entering sale.*
. . . . . .	. . . . . .	*Coroner said sale ought to be registered.* Afterwards retracted.
Dill Water put into Nepenthe bottle	. . . . . .	
. . . . . .	. . . . . .	Verdict—"Died from the effects of the medicine." Jury of opinion that it should have been labelled "poison."
. . . . . .	. . . . . .	
. . . . . .	. . . . . .	Supplied by a hospital porter.

with the result of the inquiry either in the shape of a verdict or magisterial opinion. In this column, in italics, will also be found references to several cases in which officials have censured the conduct of druggists in the sale of poisons, such censure having been itself founded upon an erroneous reading of the Pharmacy Act. As this portion of the question is now under the consideration of the Council, with a view to supply officials with more correct information respecting the Act, these cases will not be without interest.

In placing this table before the readers of this Journal, it is satisfactory to point out the small number of cases in which accidental poisoning was palpably due to ignorance or negligence on the part of druggists—much more frequently it is to the misuse of drugs or medicines by those who have purchased them that disastrous consequences are to be attributed. Again, it is satisfactory to observe so few instances of actual disregard of the provisions of the Pharmacy Act in respect to poisons, and to note that during a period extending back to within a few months after the Act came into operation, there has been an entire absence of any case in which poisoning has been the consequence of mistakes due to defective storage of poisons on the part of druggists.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

April 30th, 1872.

Present—Messrs. Ainslie, Aitken, Buchanan, Gilmour, Kemp and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MAJOR.

Three candidates presented themselves; of these, *one* failed. The following *two* were declared duly qualified to be registered as pharmaceutical chemists:—

Sant, George................Atherstone.
Henry, James Hay ....Macduff.

The above names are arranged in order of merit.

MINOR.

Nine candidates presented themselves; of these, *two* failed. The following *seven* were declared duly qualified to be registered as chemists and druggists:—

*Young, John..................Edinburgh
*Hilston, David P...............Lanark.
Shearer, John ....Wick.
Gowans, James ....Edinburgh.
Lindsay, Robert ....Lasswade.
Hosie, John ....Aberdeen.
Graham, Alexander ....Leith.

The above names are arranged in order of merit.

MODIFIED.

Four candidates presented themselves; of these, *two* failed. The following *two* were declared qualified to be registered as chemists and druggists:—

Burdon, Thomas A. ....Durham.
McNeil, Margaret ....Glasgow.

* Passed with Honours.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The sixth meeting of this Society was held in the Library, on Wednesday, April 10th, 1872; the President, Mr. E. BROWN, in the chair.

The minutes of the former meeting having been read and confirmed, Mr. S. JEFFERSON, F.C.S., gave a very interesting lecture on oxidation, illustrated by experiments.

A cordial vote of thanks was given to the lecturer on the motion of Mr. JAS. ABBOTT, seconded by Mr. WEST, Associate.

The seventh meeting was held in the Clergy Room, Church Institute, on Wednesday, April 24th; the President, Mr. E. BROWN, in the chair.

The minutes of the former meeting having been read and confirmed, Messrs. J. P. Hardcastle, W. T. Place, William Sykes, J. Lockwood, E. Battye, and A. Burton, were elected associates.

The PRESIDENT requested the Honorary Secretary, Mr. E. YEWDALL, to read the report of the Committee, referring to the prizes offered at the early part of the Session. This report explained that the Committee were enabled to offer Bentley's 'Manual of Botany,' and Attfield's Chemistry, or two other works of similar value for the best essays upon "Cinchona Barks—the history, varieties, preparations of, and Alkaloids obtained from;" and "The preparations of iron, officinal and non-officinal." Also Lindley's 'School Botany,' and Galloway's 'First Steps in Chemistry,' or two other works of equal value for the two best papers upon "Rhubarb, the history and preparations of;" and "Magnesia and its officinal preparations."

The essays were to be compiled and written by Associates, the last two subjects being confined to associates under 21 years of age.

Six essays were received, and the Committee was pleased to find in Mr. Schacht, of Clifton, an agreeable collaborator, to whom the essays were forwarded for examination. Mr. Schacht's report upon the merits of each paper was readily accepted by the Committee, and the prizes awarded as follows:—

Cinchona Barks..........Mr. West.
The preparations of Iron...Mr. F. Walbran.
Rhubarb................Mr. G. S. Highmoor.
Magnesia...............Mr. C. Smith.

The essay upon Cinchona Barks and the preparations of Iron were then read by their respective authors.

A discussion then took place as to the course to be adopted with reference to the other essays, the lateness of the hour preventing their being read, when it was resolved that the meeting be adjourned.

Before the adjournment the PRESIDENT presented the prizes to each successful essayist, with some very appropriate remarks.

Mr. SMEETON proposed that the thanks of the Society be given to Messrs. Harvey and Reynolds, and J. Day and E. Yewdall for their kind donation of the books just given as prizes, which was seconded by Mr. WILSON, Associate, and carried unanimously.

The meeting was then adjourned to Wednesday, May 1st.

The adjourned meeting was held in the Clergy Room, Church Institute, on Wednesday, May 1st; Mr. E. S. PAYNE, Associate, in the chair.

The Honorary SECRETARY read a letter received from Mr. Radley, of Sheffield, respecting Provincial Pharmaceutical Education, after which Mr. PAYNE, Curator, called attention to specimens of crude and refined ozokerite, tincal or native borax, and apatite, presented to the Museum by Mr. Reynolds; after which Mr. G. S. HIGHMOOR, Associate, read his essay upon "Rhubarb, the history and preparations of."

Mr. C. SMITH, Associate, also read his essay upon "Magnesia and its officinal preparations."

The PRESIDENT, who had entered the room during the reading of the last paper, explained that a letter addressed to him was an apology from Mr. Reynolds, who was prevented by another engagement from being present.

The CHAIRMAN announced that this was the concluding meeting of the present Session.

LIVERPOOL CHEMISTS' ASSOCIATION.

The twelfth General Meeting was held at the Royal Institution on Thursday evening, the 25th April; the President, Mr. E. DAVIES, F.C.S., in the chair.

Mr. T. F. ABRAHAM, on behalf of Messrs. Herrings, of London, presented a specimen of Natal aloes for the museum. Several donations to the library were also announced.

Dr. SYMES made some remarks on the desirability of pharmacists making their own preparations,—not with a view to profit, as wholesale houses working on a large scale would always be able to produce their preparations much cheaper than when made in smaller quantities, but as a means of instruction for those learning and engaged in the business.

The Hon. Secretary, Mr. J. HALLAWELL, then read a paper on

CHEMISTRY AND PHARMACY IN BRAZIL.

He said that although chemistry was worthily represented in two or three of the principal cities of Brazil, by medical men, and those connected with the universities and medical schools, yet everywhere practical or applied chemistry was in its veriest infancy, and could hardly be said to exist. Referring to the southern provinces in which he had resided many years, he said that a larger or more profitable field for a practical chemist did not exist anywhere; for, while in the large slaughter-houses the waste of valuable material was great, the means of collecting and utilizing it on a large scale were most easy. Materials of all kinds are abundant and cheap, and the high duties paid on imported articles offer a large profit to any manufacturer. As an instance of the ease with which waste could be collected, he stated that in some slaughter-yards a great number of vats were worked, in which the bones were macerated in order to extract the grease. The gelatine, however, runs off down a trough right away into the river and is lost; about a hundredweight being thus thrown away from each vat every two days. By simply diverting the trough into cisterns several tons could be collected *per diem* without the least expenditure of labour. Its subsequent preparation for manufacture or export would be easy. This was, however, one of the least valuable of the wasted products, and only served as an illustration. Much of the beef was salted and dried, and shipped to the northern ports for food; but very often the whole carcass of the ox was thrown into the vats, for the sake of extracting the grease, the flesh being entirely lost. There had been many objections made against the process of preserving meat in use in Australia, though no doubt about the best hitherto adopted; but a good process, presenting the beef in a more acceptable form to the buyer in Europe, would be a great boon, and would be a profitable enterprise.

He mentioned that some years ago Dr. Ubatuba, Inspector of Public Health for Rio Grande, had commenced the manufacture of extract of meat. For various reasons he had only been able to make it on a small scale, but now he was extending his plant, and hoped to be able to produce it in considerable quantity. This extract had been awarded the gold medal for its excellence and superior quality by the jurors of the Workmen's International Exhibition, held in London in 1870. Messrs. Leâo and Alves, two enterprising Brazilians, had also some years ago established a factory at Porto Alegro, for pressing oils, and they had been most successful. Nearly all the castor oil used in the province was now pressed by them, from seeds grown almost on the spot; and they had added little by little to their establishment, until it had become a very large one, and a large quantity of other oils, as neats-foot, linseed, rape, and many other vegetable oils unknown here in general use, but used there by the pharmacist and for illumination, are now regularly produced by them. These gentlemen had been aided by the Brazilian Government, which was always willing to help private enterprise by advancing money at a low interest; and this willingness to assist, after many instances of failure on the part of those helped, is most noteworthy.

Passing on to pharmacy, Mr. Hallawell stated that there were two medical schools or colleges in Brazil; one in the city of Rio de Janeiro, another at Bahia. The studies and privileges of both were the same. A student in pharmacy usually, after spending a few years in service in some retail establishment, goes up to the school at one of these two places, and there he must study two years. The course of study is almost the same as that adopted in Bloomsbury Square, and the examinations likewise. After a satisfactory examination he is granted a diploma, and may begin business as a pharmacist when and where he likes; for, like England, in Brazil there is no limit placed on the number of pharmacies. A pharmacist is called a 'Boticario;' he is exempt from serving on juries, or in the National Guard, but he cannot engage in any other business, nor have more than one pharmacy. By law medical men are forbidden to dispense their own medicines; there is therefore plenty for the pharmacist to do; and while they sometimes encroach upon the province of the doctor by prescribing for casual and common complaints, they are protected by law from being encroached upon by the doctor.

Prescriptions are written in Portuguese, the language of the country, and are not copied into a book, but written upon the label of each mixture, lotion, or box of pills. This involves labels, and consequently pill-boxes of a much larger size than those used in this country. The prescription is usually retained until the amount incurred by the patient has been paid, meanwhile serving as a sort of memorandum, each repetition of the medicine being marked upon it; it is then handed over to the owner, a receipt in full of all demands. The hours of working are very long, pharmacies generally opening at six in the morning and not closing before nine or ten at night. They are open all Sundays and holidays in most places.

The law requiring two years of study is relaxed in the case of foreigners coming from other countries to Brazil, and who bring with them an accredited diploma, or other proof of qualification from the school, college, or university, where they have resided. In this case an examination like our modified one, is made; it is called an examination of competency; and it is divided in two parts, theoretical and practical. The first is made partly by written questions, partly *vivâ voce*, and if the examiners are satisfied with the answers, the candidate goes on to the practical one, where he is required to make one or two analyses, prepare from memory one or more pharmaceutical preparations or formula, detect the presence of some adulterations in one or more substances, and recognize those in the collection of Materia Medica, and finally dispense one or more prescriptions. If this is also satisfactory, his diploma is endorsed, and he may also begin business when and where he may please in the empire.

The charges for medicine varies much with the locality; the average would perhaps be about double those charged in a first-class pharmacy in England.

Patent medicines and specialities are very largely used; many of those approved by the academies of medicine in Paris and elsewhere being prescribed by the physicians, such as, for instance, the pills of Vallet or Blancard or other accredited preparation. One excellent regulation exists, no patent medicine is allowed to be advertised in the newspapers, unless the formula has been submitted to and approved by the Imperial School of Medicine. This law is evaded in some of the smaller towns, but it is rigorously observed in the principal cities.

The Pharmacopœia recognized in Brazil is the formula of Dr. Chernoviz, a compilation from most European Pharmacopœias, but chiefly from the French codex.

Samples of the extract of beef alluded to, made by Dr. Ubatuba were shown, and the preparation was found to be very good indeed, the flavour of the beef being admirably preserved.

Oils and other products made by Messrs. Leão and Alves were shown and found well made, and several other preparations which Mr. Hallawell brought for inspection were examined with interest.

A vote of thanks to the Hon. Secretary, moved by Dr. Symes, seconded by Mr. Davies, terminated the proceedings.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, May 2nd, 1872. Dr. Frankland, F.R.S., President, in the chair.

When the minutes of the previous meeting had been read and confirmed, the President called on Mr. E. Riley to deliver his lecture "On the Manufacture of Iron and Steel." The lecturer in his discourse treated principally of the elements associated with iron in the pig, and the part they play in the subsequent conversion of the pig into wrought iron and steel. After describing the composition of the principal varieties of pig, he considered the effect of the presence of the elements carbon, sulphur, phosphorus and silicon in various proportions, remarking that the carbon, and perhaps the silicon, do not seem to be chemically combined with the iron in the pig, but simply to be diffused through the mass. In conclusion the author described the process of puddling by machinery, with especial reference to Mr. Dank's machine.

This able and exhaustive memoir was copiously illustrated by analyses.

After an animated discussion the meeting adjourned until Thursday, 16th May.

Eight communications were announced for the next meeting.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Monday, May 6th.

Public Health Bills.

The Committees on the Public Health Bill, and the Public Health and Local Government Bill were deferred till Monday next. In reply, however, to a question put by Lord R. Montagu, on Tuesday night,

Mr. Gladstone said that the Public Health Bill would not be taken at the first order on the Monday after the holidays, as it was the custom to take Supply on that night.

Wednesday, May 8th.

Juries Bill.

The second reading of the Juries Bill was put off till Monday next.

Alleged Poisoning by a Vermin Killer Containing Strychnine.

An adjourned inquest was held on Saturday, April 24, at Newton Moor, Manchester, to inquire into the circumstances attending the death of a married woman named Hickling. It appeared that on the 12th ult. the deceased feeling unwell, her husband, at her request, procured for her a worm-powder from Mr. Brunt, druggist. After she had taken the medicine, with castor-oil, she was seized with tetanic convulsions and died in half an hour. The husband afterwards went to the Manchester Infirmary, where deceased had been an out-patient, and applied for a certificate of death, saying that his wife, while sitting up in bed, had suddenly become faint and died. An inquiry having been instituted, and a *post-mortem* examination ordered to be made by Dr. Beecroft, that gentleman was convinced that the death had resulted from poison. The contents of the stomach and liver were, therefore, placed in sealed jars, and sent to Professor Crace-Calvert for analysis.

Professor Frederick Crace-Calvert said he received the jars mentioned, and examined the contents. He analysed a portion of the contents of a glass bottle containing *kousso*, and found it genuine. It contained no strychnine. He tested for strychnine, but it did not contain any. He then opened the jar containing the stomach and its contents, and analysed them specially for strychnine, of which he found (for strychnine) a large quantity. The evidences of strychnine were unmistakable. What he found in the stomach was quite sufficient to account for death. Professor Calvert here said he thought it would be an advantage, as this poison was used very frequently, and as it was very difficult to detect, if he stated the means he had employed in its detection in this case, as it might be of advantage to medical men. It was a method he had himself discovered, and he had adopted it several times before with success. The process consists in boiling the contents of the stomach with a small quantity of sulphuric and hydrochloric acids. The whole is concentrated and thoroughly mixed with an equal volume of chloroform by agitation, and allowed to stand. The chloroform which separates contains nearly the whole of the strychnine (or most of the other alkaloids) present in the contents of the stomach. The chloroform solution is mixed with a little hydrochloric acid, and evaporated nearly to dryness. The residue is then dissolved in water, and placed to dialyse. To still further isolate the strychnine from impurities, the dialysed liquor is evaporated nearly to dryness, and mixed with a little caustic potash and chloroform, when the latter dissolves the strychnine, which is obtained in a state of purity on evaporating the chloroform. A very nice modification of the application of the bichromate of potash test, proposed by Otto, consists in adding to the strychnine a cold saturated solution of the bichromate, when a yellow crystalline precipitate is produced. The excess of bichromate is then washed carefully away, and concentrated sulphuric acid is produced, which has a far greater permanence than that obtained by the usual method.

Evidence was also given by a little boy that, about the time the deceased's husband was known to be in Hyde, on the same evening the woman died, a man dressed in similar clothes to those the husband had on met him in the street, and sent him to the shop of Mr. Oldfield, druggist, for three vermin powders.

Henry Oldfield said he was a chemist and druggist, and resided at Hyde. He manufactured vermin destroyers—a powder. Each powder contained about a grain and a half of strychnine. The other portions are composed chiefly of starch powder and blue colour. He was in the shop all the evening when the witness said he bought these packets, but he had no recollection of seeing him. Every packet containing the vermin killer was labelled "poison" in three or four places, and they were charged threepence each.

The jury returned a verdict of wilful murder against the husband, and the coroner committed him for trial at the Chester assizes.

On the following Monday, the prisoner was brought up before the magistrates. The evidence was substantially the same as that given before the coroner. Mr. Oldfield stated in addition that he formerly registered the sale of these powders; but, in consequence of a difference of opinion as to whether it was necessary or not, he gave over doing so, and was not registering them on the 12th of April. He did now, however, register them.

The prisoner was committed for trial on a charge of wilful murder.

The following correspondence on the above subject has during the week appeared in the *Manchester Courier*:—

Sir,—I believe our law has imposed certain important restrictions on the sale of poisons. If that be so, has there not been an evasion or disregard of its provisions in connection with the death of Mrs. Hickling, of Newton? Your report of the adjourned inquest stated that "evidence was called to prove that about two hours before the woman's death the husband was in Hyde, and sent a lad to purchase three vermin powders at a chemist's shop, for which he paid ninepence. Each of those powders contained a grain and a half of strychnine." I think you will agree with me that a very important question is involved in the correctness or otherwise of my impression, and I should like to be satisfied on the subject. I trust you will accept that desire as sufficient apology for troubling you.—Yours, etc.,

JUSTICE.

Manchester, April 29th.

Sir,—In reply to your correspondent "Justice," I wish to say that by the "Sale of Poisons Act" a number of articles specified as "poisons" and enumerated in a schedule are not allowed to be sold except under certain conditions. This schedule is divided into two parts; the articles in the first part, in which strychnia is included, being of a more dangerous nature, are not to be sold unless the sale be registered in a book kept for that purpose, and the entry signed by the purchaser, who must either be known to the seller or introduced by some one known to him, who must in that case also sign the book. The articles in the second part of the schedule being of a less dangerous nature do not require registration, but must be labelled with the name of the article, the word "poison," and the name and address of the vendor. Now in this second part of the schedule we find "vermin killers (every compound containing a 'poison,' and sold for the destruction of vermin)." I conceive, therefore, that if the druggist who sold the vermin powder in the case mentioned put his name and address on each packet, he has neither evaded nor disregarded the provisions of the Act.—Yours, etc.,

W. WILKINSON.

263, *Cheetham Hill, Manchester, April* 30*th*.

Sir,—I thank Mr. Wilkinson for the information he has kindly given on the subject of the sale of poisons; but he omits mention of the very question which I considered of most importance, although I know I did not specify it. I have the impression that the sale is prohibited to children, whilst in the case alluded to it was sold to a lad who received a halfpenny for his trouble, and therefore a mere child or little more.—Yours, etc.,

JUSTICE.

May 2*nd*, 1872.

Sir,—It did not occur to me that the question of your correspondent "Justice" had special reference to the age of the person to whom the poison was sold, or I would have replied to it in my letter yesterday. The Sale of Poisons Act does not contain any restrictions as to the age of the persons to whom the article is sold. An Act relating to the sale of arsenic, passed some years ago, does prohibit the sale of that article to persons not of full age; but in the recent Act to regulate the sale of poisons age is not mentioned; the prohibition in the use of arsenic, however, still continues in force. If your correspondent will favour me with a call, I shall be glad to show him copies of both Acts. I may add that I have learned that the packets of vermin killer in question were properly labelled with the name and address of the druggist, and the word "Poison" in prominent letters.—Yours, etc.,

W. WILKINSON.

263, *Cheetham Hill, Manchester, May* 3*rd*, 1872.

POISONING BY CARBOLIC ACID.

An inquest was held at Rotherham, on Friday, May 3rd, to inquire into the circumstances attending the death of Eliza Pye, a child five years of age.

Eliza Adams, who had adopted the child when its father died, said that the deceased child and another, whilst playing, had drunk some liquid from a bottle that she had obtained, as a disinfectant, from the Board of Health premises. She did not know until afterwards that the disinfectant was carbolic acid, and was not told that it was poison at the time it was given to her. She fetched it in an ordinary ginger-beer bottle.

The coroner expressed an opinion that a label should be placed on vessels containing these disinfectants, showing that they were poison, or that the persons to whom it was given should be cautioned as to its dangerous nature. He did not see why any distinction should be made between druggists and those who dispensed poisons as disinfectants at the Board of Health. The former were compelled to place a label upon the vessel or packet denoting that what they sold was poisonous, and they were obliged to give a caution to the persons receiving it as to their dangerous nature, and he thought the same should apply to the local authorities.

A verdict was returned by the jury that the deceased died from the effects of drinking carbolic acid, and appended to the verdict an opinion that the delivering out to persons of carbolic acid without a label, caution, or information of its character is dangerous, and should be discontinued.

The deputy-coroner said he would forward this expression of opinion by the jury to the proper local authorities.

American Diplomas.

On Tuesday, May 7th, an appeal was argued in the Court of Exchequer on behalf of Thomas Andrews, of Shrewsbury, against a conviction by the magistrates of that town for improperly using the letters M.D. after his name in accounts rendered. The appellant produced a diploma of the University of Philadelphia, United States, of the year 1870, but did not appear even to have visited the place or been examined before a qualified tribunal.

Their Lordships were all of opinion that the conviction should be affirmed, and dismissed the appeal with costs.

Baron Martin expressed his satisfaction that measures were being taken by the Legislature in America to suppress this issue of spurious degrees by the University of Philadelphia.

Obituary.

GEORGE ROBERT GRAY, F.R.S.

We regret to have to record the death, on Monday, May 6th, of George Robert Gray, F.R.S., Assistant Keeper of the Department of Natural History at the British Museum. Mr. Gray was the youngest son of Samuel Frederick Gray, author of the well-known 'Supplement to the Pharmacopœia.' The deceased gentleman was himself the author of some highly esteemed works on various branches of natural history.

GEORGE JOHN GILES.

George John Giles, late of the Seven Sisters Road, Holloway, died at Whiteparish, Wilts, on the 25th day of April, from pulmonary consumption, in the 25th year of his age.

MEETINGS FOR THE ENSUING WEEK.

Monday.........*Society of Arts*, at 8 p.m. — "Silicates,
May 13. Silicides, Glass and Glass Painting." By Professor Barff (Cantor Lecture).
Royal Medical and Chirurgical Society, at 8.30 p.m.
London Institution, at 4 p.m.—"Elementary Botany." By Professor Bentley.

Tuesday ......*Royal Institution*, at 3 p.m.—"Develop-
May 14. ment of Belief and Custom." By Mr. E. B. Tylor.

Wednesday ...*Pharmaceutical Society of Great Britain*,
May 15. at 12.—Annual Meeting. Evening, at 8.—Conversazione.
Society of Arts, at 8 p.m.

Thursday......*Royal Society*, at 9 p.m.
May 16. *Royal Institution*, at 3 p.m.—"Heat and Light." By Dr. Tyndall.
Chemical Society, at 8 p.m.

Friday ....*Royal Institution*, at 9 p.m.

Saturday......*Royal Institution*, at 3 p.m. — "Chemical
May 18. Action of Light." By Professor Roscoe.

Election of Council.

Sir,—The letter of 'Fair Play' alludes to the omission of the names of some of the candidates, mine amongst others, in the list which has been circulated by the Defence Association. Apart from its unfairness, I think it bad taste to send such circulars to those also who are thus blackballed by anticipation, soliciting them to vote against themselves.

I have been invited for several years to allow my name to be placed on the list, and have acceded on the present occasion, feeling that when new names are required, it is but reasonable to expect that those who have for years been connected with the Society, and shared whatever benefits have arisen therefrom, should be ready, if requested, to take their turn in carrying on its business and promoting its general welfare. I really know nothing of the Defence Association or its officers, and greatly doubt if they know much of me or my views. It would be therefore obviously unfair for either to denounce the other. There must be great and important interests to serve; and were I on the Council I could only give any question my best consideration and judgment, free from influence outside or in. Beyond that I can promise nothing, except that I shall not feel disappointed at a non-election, seeing there are so many excellent men ready to fill the vacancies that now occur.

It is to be regretted the Association should have issued the circular as emanating from the Pharmaceutical Society itself. The discovery of the misrepresentation would lead respectable readers to disregard the contents. "Qui mendax in uno, qui mendax in omnibus." Edward M. Burden.

Sir,—What a fuss Messrs. Smith and Co. are making about the Defence Association's circular! Mr. Smith surely forgets that his name was not only on a similar list last year, but that it was put there at the particular request of his friend Mr. Carr, and that his election was secured thereby; and further, that no protest or threat of legal proceedings was made by him at that time. Verily, the inconsistency of some people is passing strange. But the whole matter seems to lie in a nutshell; had the promoters of the circular placed Mr. Smith's name on the list, there would certainly have been nothing said about the circular "purporting to emanate from the Society," or of its "having a tendency to vitiate the whole election," from the Torquay quarter at least. As it is, however, I think he has, with the assistance of the Council, helped on the object of the Defence Associations very considerably; and had they known their circular was to be brought so prominently before the members through the Journal and otherwise, they might have saved themselves the expense of advertising.

I have not the least doubt but what the members will ratify the selection made by the Defence Committees, and show by their decision that they were right, at least, in excluding the names of Messrs. Smith and Carr from the list of gentlemen who have yet to make a public apology to their constituents for their actions in regard to the poison question last year.

As regards your editorial note, Mr. Editor, I cannot see how it could be possible for any man with a grain of common sense to mistake the Defence circular for the Society's official voting-paper. The parties who sent them in return to the Secretary as such, must have been opponents,* who did so for a purpose best known to themselves.

A word to your correspondent 'Fair Play.' Did it not occur to him, when he wrote his communication, that anonymous writing is anything but fair play? When he was so extremely anxious for the independence of individual members, he might have shown his own independence by giving his name. But I deny that there is anything in the circular that need be protested against. The heading might certainly have been worded differently, or some of the wording might have been transposed, which would have suited the requirements of the Defence Committee and left them free from the accusation that has been made against them of usurping the name of the Pharmaceutical Society; but as it is, it shows no indications of such, and I can confidently assert that such

* We are informed that Mr. Fairlie's assumption is incorrect.—Ed. Ph. J.

an idea was far from the thoughts of the composer at the time it was written; and further, I do not believe that any member of the Society could take any such meaning from it. This cry, got up by Messrs. Smith and Company, resembles very much drowning men catching at straws. 'Fair Play' complains that there are not sufficient London men on the Council. But whose fault is it? Certainly London chemists themselves: they have nominated the half of the candidates standing, whereas if they had united upon the half of that number they might easily return them all, and I am certain the provinces would not object. He also puts forth the claims of several gentlemen, while condemning the action of the Defence Committees. Mr. Savory we know by name, and Mr. Carr we know to our cost; but, as a provincial member, I have to ask who are Burden, Malden, Stacey, and Starkie? If would-be candidates do not think it their duty to let their opinions be known, they do not deserve the support of the members.

J. M. Fairlie.

Sir,—I have read with much interest Mr. Urwick's letter in yours of the 20th inst., and think that it would be wise if all the gentlemen nominated would express their opinions in the straightforward manner he has done.

With regard to the compulsory regulations, I fancy there is a very great chance that this question will eventually die out, and that there will be no need for the Government to make compulsory regulations which to the majority of the profession will be always looked on as obnoxious.

The returns of the Examining Board show that only men properly qualified are now admitted into our ranks, and all danger of negligence is to a certain extent avoided.

But it is not so much to this point I wish to draw the attention of your readers, as to the latter portion of Mr. Urwick's letter, and I hope the Council may be prevailed on to place all on an equal footing, for as he remarks, the difference in the public mind is very slight, and it is comparatively few who know the distinction between member of the the Pharmaceutical Society, pharmaceutical chemist, and chemist and druggist, by examination.

It is to my way of thinking only right that the men who have passed the Board of Examiners should have a different title to those who only acquired it by having been in business before a certain date.

I trust should Mr. Urwick be successful in obtaining a seat at the Council Board, he will bring forward this important question.

April 29th, 1872. Chemist and Druggist.

Provincial Education.

Sir,—I do not hold the narrow views imputed to me in your leader of May 4th, nor will anything I have written fairly warrant such a conclusion. The recent action of the Council has strongly justified the opinions expressed in my short letter on Provincial Education, page 338, Pharmaceutical Journal.

In claiming grants for provincial education, we believe we are in strict accord with the original intentions of the founders of the Society; men whose aim and object was to elevate and benefit the whole body of chemists and druggists.

Thirty years ago, 1843, the Council in their annual report, "assured the country members that the establishment of provincial schools, and the extension of means for facilitating education throughout the country, locally, has by no means been lost sight of," and the same report further says, "It is evident that the provincial schools of pharmacy must be assisted, in the first instance at all events, with grants of money." In 1843 advances were made to branch schools to the amount of £221, and in the following year £90; unfortunately just at that time a change took place which resulted in a loss of income to the Society of about £3000 a year, and of course no more grants could be made. From this it will be seen we are simply going back to first principles. We ask no eleemosynary aid, nor have we any nefarious designs on the funds of the Society.

Referring to the report in the Journal, it is evident the Council are now alive to the importance of this question. Some of the speeches were not only just, but generous. I do hope, however, there will be no undue haste in this matter; what is needed is not merely money, but a well-digested and comprehensive scheme likely to secure the best results, and to give stability to local efforts by affiliating the associations as branch schools with the Parent Society.

We have not asked for a grant in Hull, although we have established lectures, classes, etc., at considerable cost, to which all assistants and apprentices in the trade have access on equal terms. Our botanical lectures opened last week at the Botanic Gardens, with a class of 24 present, of whom 18 were assistants and apprentices.

I regret that Hull, like all other towns, has so small a proportion of members of the Society, viz.: 19 out of 90 in business; we do not, however, forget the benevolent fund, to which we have 37 subscribers.

It is gratifying in one respect to know that the school of pharmacy in Bloomsbury Square derives its chief support from country students.

Hull, May 7th, 1872. James Baynes.

[*** Mr. Baynes is mistaken in supposing that we regard the view put forward in the letter he refers to as being a narrow one. On the contrary, our objection to the argument he and others have based on the fact that country members have contributed largely to the educational establishment in Bloomsbury Square, is that it is illogical, inasmuch as it is not country members who now require the aid of the Society, but for the most part others who have never contributed to its funds. We fully concur with Mr. Baynes in his estimate of the original intentions of the founders of the Society; but we must also remind him that they distinctly pointed out that it was only by the joint assistance of the whole body that the foundation could be laid for systematic education. However, we cordially agree with him in hoping for the speedy organization of some comprehensive educational scheme, that will be for the *general* good of the trade, in accordance with the Society's original aim and intention.—Ed. Ph. J.]

Benevolent Fund.

Sir,—The Pharmaceutical Society, and more especially its unfortunate members, are much indebted to the late Mr. Orridge for the vitality now manifested in the working of the Benevolent Fund, which, for many years from its commencement, was little better than an abortion; but, however much the present is an improvement upon the past, Mr. Scholefield has shown in your issue of a fortnight ago, that there is yet great room for improvement. As local secretary, I have made many applications on behalf of the fund, and have frequently met with refusals on the ground that misfortunes near at hand, and calling for immediate relief, had much stronger claims than a fund from which the unfortunate of the present generation could derive so little benefit, compared to the sacrifices made by the subscribers, who are in many cases at least, as far removed from affluence as they are from indigence. I have constantly felt that such objections were both natural and forcible, and that I could not reasonably urge a donation. I cannot see any grounds upon which pharmacists of the present day should be expected to tax themselves for the relief of necessitous members of their calling in future generations. The present race have had to struggle against inordinate competition and other difficulties, from which the coming generation will be saved by the operation of recent legislation. I see no reason to doubt that the pharmacists of twenty years hence will be a better remunerated class; they will include fewer poor, and a greater number of well-to-do members. There will be fewer demands upon their charity, and greater ability to meet those demands. Why then should we be taxed to relieve them of the responsibility, or, perhaps I should say, to deprive them of the pleasure which the prosperous tradesmen must always feel in mitigating the suffering caused by such misfortunes as were not provided against, because they could not be foreseen? Our present bye-laws require that all donations shall be invested, and not applied to current requirements, but I see no reason why the whole of the annual subscriptions, as well as the interest upon funded capital, should not be applied to the alleviation of present necessities.

"Sufficient for the day is the evil thereof."

I trust that some member of the incoming Council will make this subject his hobby, and ride it home, and that in the meantime some other local secretaries will give us the benefit of their experience, and account for the small number of subscribers to be found in many a flourishing town.

Barnard S. Proctor.

April 30th, 1872.

Early Closing.

Sir,—It may assist the early closing movement, when I mention that for years I have had the window and door shutters put up at 8 P.M., and I hope others will now follow my example, and that we shall soon see the absurd plan of keeping up one shutter and keeping another shutter down, like coloured bottles, "things of the past."

William T. Cooper.

26, *Oxford Street, London.*

The Profession of Pharmacy.

Sir,—In a recent letter appearing in your pages from the pen of Mr. Rimmington, the term "Profession" with a note of interrogation after it occurs, implying, I presume, the writer's doubt as to the correctness of the term. As several of your correspondents have latterly made considerable use of the word when writing of our calling, it may not perhaps be considered out of place to inquire how far we are warranted in the use of the word. My own impression is that in writing or speaking of our business as the "profession of pharmacy," we allow zeal to outrun discretion. Strictly speaking, and according to general usage, "profession" means a calling or vocation by which a livelihood is obtained through the medium of a special branch of science, law, or literature, in contradistinction to "trade," which implies a trafficking in goods for the sake of profit. Now without doubt our daily occupation must be classed under the latter term; we are mere dealers or traffickers in goods. We may possess a well-fitted laboratory for the preparation of pharmacopœia compounds, or for scientific investigation, and our shelves may be well-filled with pharmaceutical preparations; but our counters and cases are stocked with perfumery, soaps, toilet requisites of every conceivable description, pickles and sauces, grocers' sundries, tobacco and cigars, seeds, etc.; our cellars with oils and colours, and odds and ends of nearly every trade under the sun. Does the sale of these accessories with drugs suffice to rank us with professional men?

That there exist pharmacies where the drug trade almost pure and simple is carried on I know, and I admit that the proprietors of such, and even of others, by reason of superior scientific attainments, may almost lay claim to professional rank; but in the majority of establishments, the sale of pharmaceutical preparations forms only a small portion of the returns, and so trading has to be tacked on to what might otherwise constitute the elements of a profession.

We all look forward to the time when the interests of pharmacy will be confided to the care of a more highly educated class of men; when medical men will confine themselves strictly to their own special branches of science, leaving dispensing to those who devote their time and money to its study and work; and when even stricter examinations will tend to reduce the number of aspirants to its ranks. Then, and not till then, will the dispensing and preparation of drugs alone be sufficiently lucrative to induce the followers of pharmacy to tear from its stem the parasitic growths which at present encumber it, and so render it worthy of the appellation "Profession of pharmacy."

M. J. Ellwood.

Leominster, April 30th, 1872.

Who Shall Dispense?

Sir,—I am obliged to you for inserting my letter in last week's Journal, but in common with many other would-be writers, I find that the letter does not express so explicitly as I would wish the idea I desire to impress on the members of the trade.

With your permission I will submit the following propositions:—

Thanks to the efforts of the late Jacob Bell and others, chemists, as a body, hold a far better position than formerly For the future a severe educational test will be applied to all entering the trade. This education must involve a great outlay both of time and money. The present state of things leaves so small a proportion of dispensing in the hands of chemists, that few persons of good position will care to bring up their sons to the calling, and the evident tendency of the trade is to restrict the chemists' business to dispensing.

Being now by law recognized as an educated body—being by law compelled to assume great responsibilities, I contend that it is a duty to ourselves and to those who may come after us, to make the calling worthy of the education and responsibility. This can only be done by making the chemist (call him pharmacist if you like) the only recognized dispenser of medicine.

I know that this proposition involves a great deal, that it will take time and occupy far abler heads than mine to work out the problem, but I want to set the idea before the members of the trade (I would avoid the term profession yet awhile). From conversations I have had with different members of the medical profession, I feel confident they will willingly assist us; but we must bear in mind that when they cease to be dispensers, we must cease to be prescribers.

Henry Lawrence.

Kensington, W.

Preliminary Examination.

Sir,—I think you would have a decided improvement in the answers of candidates sitting for the above examination, if a little more time was allowed, say an hour and a half to each subject, making a total of four and a half hours for the whole. If the twenty questions given by the Board of Examiners be answered in three hours, it is only an average of nine minutes to each, and allowing twenty minutes for the composition question, it makes even that average considerably less.

Then again, I think that some little consideration ought to be made in the case of candidates who were apprentices previous to July, 1867, or many youths must forfeit that which would have been the result of a large premium, or in other words, have their prospects blighted for life. It is almost impossible for a youth to so ground himself in English grammar (after having left school for several years) as to answer such questions as the following:—"Into how many classes are adverbs of time divided? Give several examples of each." Will it not be well for preliminary candidates to state on the form of application, if they were in the profession before the passing of the Act or not?

One who Failed on April 8th.

A. Strachan.—Your letter has been handed to the Secretary.

M. J. Ellwood.—'How Crops Grow,' published by Macmillan.

C. Andrews.—A retailer of beer, spirits and wine can sell under his licence rectified spirits of wine, but he cannot, under any circumstances, sell methylated spirit on the same premises; nor would the revenue authorities grant a licence to sell methylated spirit to a retailer of beer, spirits and wine on the premises on which these goods are sold.

G. C.—(1) Phosphate of lime with colouring matter. (2) Yes. (3) The deposit cannot be utilized, as it is less soluble in the acid than when first made.

O. J. Rivett.—Chloride of sodium does not burn. The colour of the flame is due to the vaporization of a small portion of the chloride.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

PSYCHOTRIA EMETICA—Striated Ipecacuanha.—This is little known to British commerce,* and not obtainable through the ordinary channels of trade, except perhaps at rare intervals. Hence, I suspect it is not so commonly used as an adulterant as is generally supposed. Its structure is so like that of *Caphaelis* that a very brief notice of it will suffice. Careful observation alone could enable the analyst to suspect its presence as an adulterant; and he would hardly be justified in pronouncing positively about it without the corroborative evidence of chemical analysis. The difference between these two Ipecacuanhas are in degree rather than in kind, so far as relate to their microscopic anatomy. The cells of the medulla in *Psychotria* are larger, more pitted, and more disposed towards secondary deposits. Their contents, starch granules, vary too much in size and shape to afford the basis of correct diagnosis; but the granules are less aggregated than in *Cephaelis*. The cells of the wood zone are larger in *Psychotria* and are much more thickened with sclerogen deposits. If a transverse section be treated with acidum nitricum (B. P. strength) for five minutes, and removed to a drop of pure glycerine, in which it is allowed to macerate for about ten minutes before being transferred to fresh glycerine for observation, the successive layers of the sclerogenous deposit will be beautifully demonstrated. The outline of these wood cells, as seen in transverse section, is less decidedly angular than in *Cephaelis*, but is less oval than in *Richardsonia*. As in *Cephaelis*, they contain starch granules, but their pitting is more pronounced than in the true Ipecacuanha, but the cells appear more independent of each other and more easily isolated. The cells of the cortical zone are very irregularly shaped, have exceedingly thin walls, and vary much in size near the woody zone, at the circumference of which they approximate to the pleurenchyma cells of the ordinary vascular sheath, spiral vessels being absent. A few raphide receptacula are present, the raphides being acicular. The botanical characteristics of the two Ipecacuanhas are too well known to require comment, and are much more striking than the microscopic ones.

RICHARDSONIA SCABRA.†—This I suspect is much more commonly present in pulv. ipecacuanha than the foregoing, and is fortunately much more easily recognizable, though its general structure accords with that of *Cephaelis*. It is much more easily distinguished from either of the others by its ordinary botanical characters than by its microscopical, through the absence of medulla, and the great proportion of starch can leave but little doubt as to its presence or not in any given powder.

The diameter of the wood zone is exceedingly small in proportion to that of the cortical zone. The woody fibres resemble those of *Cephaelis* more than the fibres of *Psychotria*, but in some of them a spiral deposit may be made out with the aid of nitric acid, a high power and careful illumination. They are much more regular in outline, as seen in transverse section, and are somewhat oval, sometimes nearly circular. The cells of the cortical zone are more regular than in either of the others, and in horizontal section are often hexagonal in shape; are full of starch, which lies somewhat loosely within the cells. The starch granules differ in shape from those of *Cephaelis*, being more angular, and less disposed to form aggregate granules. Their polariscope reaction appears to be identical. In addition to the adulterants named in my notes on *Cephaelis*, I will now mention the starch of *Arachis hypogea* the origin of which troubled me for a long time until a friend kindly gave me a piece of oilcake, which he said was adulterated with "ground-nut buffum," and I recognized therein an old but nameless friend I have repeatedly met with in cocoa and chocolate, and but yesterday in *fresh butter*.*

(*To be continued.*)

* Mr. Jas. Collins, in kindly replying to some queries about it, informs me he has seen but one parcel in the market.

† The specimens from which my description is taken were procured through commercial channels by the kindness of my friend Mr. R. Bellamy, of Hull. I am in consequence not confident as to the correctness of the specific name. They reached us unnamed.

Since the foregoing description of *Richardsonia* was sent to press, Mr. James Collins has kindly sent me a specimen of genuine *R. Scabra*, which presents many structural differences from that previously described. In the specimen now referred to, the wood zone contains numerous pitted vascular ducts of considerable size. The wood cells are somewhat irregularly distributed, but are in other respects similar to those already described. The cells of the cortical zone of the true *R. Scabra* are less decidedly hexagonal, their walls are thinner and somewhat sinuous. Their contents are starch granules, which are less angular in form, the separate granules being often round, with a distinct but variable hilum. There are fewer raphides present. The doubt expressed in my footnote is thus confirmed so far as regards the specific name of the specimen described.

* In company with salt, sugar, stearine, water, brains, etc., and sold at dairy butter price in a respectable shop, whence it wound its way to my tea-table.

SUBSTITUTION OF CARBOLIC OR PHENIC ACID FOR CREASOTE.

COMMUNICATED BY MR. T. N. R. MORSON.

The value of the wood creasote of Reichenbach as a remedial agent, and its employment in the preservation of articles used as food, has been fully proved during the forty years we have been manufacturers of this article.

Of late years its reputation has suffered from the substitution of carbolic or phenic acid for true creasote; and as no good test to distinguish these bodies has been published (and those of our Pharmacopœia are for this purpose useless), we shall feel obliged by your publishing a very simple means for distinguishing these two bodies, which my son, Mr. Thos. Morson, has discovered in making some experiments on adulterated samples submitted to us. This test is glycerine, in which true creasote is *insoluble, or nearly so*. Carbolic or phenic acid, on the contrary, *dissolves in all proportions*, and any large amount of this latter substance, if mixed with true creasote, will render the creasote soluble.

The danger of substituting carbolic or phenic acid for creasote to be used internally or for food is well known.

To test a suspected sample, mix it with an equal quantity of pure glycerine. If they unite and make a clear solution, the substance is carbolic acid, or in greater part consists of it.

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.

BY C. R. A. WRIGHT, D.SC.

(*Continued from page* 885.)

The portion of the first Na_2CO_3 precipitate insoluble in ether is dissolved in HCl, and fractionally precipitated by Na_2CO_3, to remove colouring-matters as much as possible; the last precipitate, after thorough washing and drying, forms a light buff-coloured amorphous powder that does not soften at 100° when perfectly dry, but clots to a resinous mass if heated in the water-bath while still moist; it is soluble in alcohol, is precipitated from this solution on addition of ether, and yields salts that have no vestige of crystalline characters.

Both the crystalline and the non-crystalline hydrochlorates yield on analysis numbers identical with those required for codeia hydrochlorate; for the reasons developed in the subsequent sections, they are regarded as respectively di- and tetra-codeia.

The filtrate from the original Na_2CO_3 precipitate contains much unaltered codeia; by extracting with ether and agitation of the extract with excess of phosphoric acid solution, a mixture of phosphates is obtained, from which a further quantity of each polymeride is obtainable by simply boiling down the liquid till the boiling-point reaches 200°

The hydrochlorate of tetracodeia obtained as above described forms a brownish brittle tar not fusible at 100° when dry; dried at 100° it yields the following numbers:—

Specimen A. 0·325 grm. gave 0·773 CO_2 and 0·186 H_2O.
„ B. 0·3145 „ 0·732 „ 0·185 „
0·1215 „ 0·0495 AgCl.

	Calculated.		Found.

In appearance and most physical properties tetracodeia and its salts bear a great resemblance to chloro- and bromo-tetracodeia; and they further agree in that all yield a blood-red colour on warming with silver nitrate and nitric acid, or with nitric acid alone; it differs from chloro-tetracodeia in that the aqueous solution of the hydro-chlorate does not precipitate on the addition of strong HCl, the salt being apparently as soluble in diluted HCl as in water; also the free base does not oxidize so readily. In all respects tetracodeia agrees with the description given by Anderson of his "Amorphous Codeia"* obtained by the action of sulphuric acid on codeia; on comparison with the product obtained by Anderson's process, no essential differences could be detected between the two substances, except that the phosphoric acid product was somewhat darker in tint, owing no doubt to the presence of colouring-matters from the higher temperature employed in its production.

The hydrochlorate of dicodeia obtained as above described crystallizes with $3H_2O$ for every C_{18} contained, this water of crystallization being wholly lost at 100° and partially by standing over sulphuric acid.

* Anderson, Ed. Phil. Trans., vol. xx. (I), p. 57.

Dried at 100°, these crystals gave the numbers:—
0·306 grm. gave 0·719 CO_2 and 0·182 H_2O.

$C_{72}H_{84}N_4O_{12}$	1196	100·00	

If the solution of the hydrochlorate be concentrated the addition of Na_2CO_3 solution throws down tarry globules consisting of a mixture of the base and its hydrochlorate, the salt being sparingly soluble in the NaCl solution formed by the decomposition.

Dicodeia and its salts do not yield a blood-red colour with NO_3H, only a slight orange tint; $FeCl_6$, also SO_4H_2 $+K_2Cr_2O_7$, give no colour reactions.

In general properties, and in the fact that water of crystallization possessed by the hydrochlorate is lost at 100°, dicodeia bears a great resemblance to the "isomer of codeia" oqtained by Drs. Matthiessen and Armstrong by the action of diluted sulphuric acid on codeia. On comparison with the product obtained by Armstrong's process, no difference whatever was discernible provided the hydrochlorate obtained by the action of sulphuric acid, etc., were several times re-crystallised; the crude hydrochlorate contains, besides the dicodeia salt, the hydrochlorate of another polymeride, which differs from dicodeia hydrochlorate in that it is non-crystalline, drying up to a gummy, extremely hygroscopic and deliquescent substance; it yields a blood-red colour with NO_3H, and with $SO_4H_2+K_2Cr_2O_7$ a very evanescent purplish-red; Fe_2Cl_6 gives no colouration at first, but on standing a reddish-purple tinge appears, gradually becoming more intense. Na_2CO_3 throws down an amorphous white precipitate, which is soluble in ether, and but little changed by exposure to air. From these properties, which seem to be analogous in some respects to dicodeia, in others to tetracodeia, the base is considered to be intermediate between these two polymerides, *i.e.*, to be *tricodeia*. The crude hydrochlorate of dicodeia obtained by Armstrong's process on re-crystallization furnished mother-liquors which, on standing over SO_4H_2 for several weeks, gradually deposited crystals, and finally became a crystalline mass wetted with a viscid non-crystalline liquid; by gentle pressure in filter-paper the liquid portion was separated from the crystals, which were found to be only dicodeia hydrochlorate; and finally, the treacly hydrochlorate of tricodeia was extracted from the papers by water. On repetition of the treatment over SO_4H_2, no crystals were obtained; at 100° a brittle, gummy, hygroscopic substance was obtained, of which.

0.309 grm. gave 0.730 CO_2 and 0·191 H_2O.

THE FIRST ANNIVERSARY DINNER OF THE PHARMACEUTICAL SOCIETY.

On Tuesday, what will probably prove to be but the first of a long series of similar gatherings, took place at the Crystal Palace, when a company of over two hundred gentlemen connected with the Pharmaceutical Society, with their friends, dined together, under the presidency of Mr. A. F. Haselden, F.L.S., the President of that Society.

The Chairman, in proposing the first toast, said: Gentlemen,—Mine is the privilege, and I may add the honour, of proposing the first toast of the evening, a toast which always finds a ready response amongst Englishmen, viz., "The health of Her Most Gracious Majesty the Queen, their Royal Highnesses the Prince and Princess of Wales, and the other members of the Royal Family." No words of mine can add to the virtues, the many virtues which adorn our Sovereign Lady the Queen. As a lady, a parent, and a monarch, I know not where I could look for her equal. She reigns in the hearts of her subjects; her sympathies are truly with them; when they sorrow she sorrows, and when they rejoice she rejoices. The loyalty of the people of this country towards Her Majesty and the Royal Family of England is unequalled. Were it possible that any could doubt this feeling, I would simply call to their remembrance the dark and dreary days of last December, and the bright and joyous day of Thanksgiving in February. His Royal Highness the Prince of Wales enjoys the esteem and affection of the people, but, indeed, it was only when we feared we might lose him that we discovered how much we loved him. For that good, kind, amiable, loving and beloved lady, the Princess of Wales, I have only to whisper her name to make all faces radiant with smiles of approbation; and all the junior members of the Royal Family are winning the hearts and loyalty of the people. I need say no more but repeat the words of the toast, "The Health of Her Most Gracious Majesty the Queen, coupled therewith their Royal Highnesses the Prince and Princess of Wales and all the members of the Royal Family of England." These few words produced frequent applause, which was continued for some minutes at the end, and was followed by the band playing "God Save the Queen."

Mr. T. Hyde Hills proposed "The Army, Navy, and Reserve Forces," which was appropriately responded to by Captain Starkie.

Mr. Brown, of Manchester, was called upon to propose the health of the "Medical Profession." He said it augured well both for the past and future, to see so large a gathering at the first of what he hoped was destined to prove a long series of annual festivals. He was glad to think that the day had passed for any absurd jealousies between the medical profession and that of pharmacy. It must be to the interest of the medical profession that they should have as their colleagues an educated body of men, capable of carrying out their instructions, and assisting them to the fullest extent in their philanthropic labours; and the cordial understanding which now existed, had, he believed, been greatly promoted by the founders and conductors of the Pharmaceutical Society. And day by day this good understanding was increasing, especially in London, but he hoped that even in the country the happy consummation was rapidly approaching when the general practitioner who dispensed his own medicines would disappear, and his place be taken by the educated physician of the future, who would find abundant employment for the educated pharmacist. There ought not to be any antagonism between such a noble profession and those who were so closely allied to it. It had been well said—

> "A wise physician skilled our wounds to heal
> Is more than armies to the public weal;"

but an army was of no use without a general, nor a general unless his orders were intelligently and promptly carried out. The physicians of the present day were able—thanks in great measure to the efforts of the Pharmaceutical Society—to rely on their prescriptions being faithfully and properly dispensed; and he hoped, therefore, they would give pharmacists plenty to do. It was true that prevention was said to be better than cure, and, therefore, sanitary questions now occupied a prominent position, but even in that work chemists were always ready to give their aid. In conclusion he alluded to the recent illness of the Prince of Wales, and to the unremitting care and attention of his medical advisers, which, he said, was equally bestowed daily and hourly by thousands of men who looked for no honour or reward for their labours beyond that of a good conscience and the gratitude of those who entrusted their lives to their care. He begged to couple with the toast the name of Dr. Leared.

Dr. Leared, in responding, said the profession for which he had the honour to speak, was a great and glorious one, notwithstanding everything that could be said against it. Alluding to a recent article in a weekly journal, which put the question whether the world would not have been as well or better if there had never been either physicians or physic in existence, he remarked that a similar question had been put with reference to the members of a cognate profession—the Church; and there was not the least doubt that if the cynical scrawler who wrote that article were taken ill himself, he would soon enough run to a physician, get a prescription, no doubt with the cabalistic marks upon it to which he alluded, have it dispensed, and take the medicine with the full expectation of getting better. He believed an age of therapeutic science and discovery was at hand, and that in the future, more than ever, the hearty co-operation of zealous, educated pharmacists would be required.

Dr. Greenhow proposed "The Pharmaceutical Society of Great Britain," not simply as a matter of form, or because he had been requested to do so, but with all his heart, and from a thorough knowledge and appreciation of what it had done. The Society was originally a voluntary association, but upon it had now devolved by Act of Parliament a very onerous duty, in which every member of the public was interested, viz. of preparing such regulations as should ensure the proper education of all future chemists and druggists, and of testing the fitness of candidates for the duties they were to undertake. And he would venture to say, with a full knowledge of the facts, that no society could have carried out these duties with better judgment or more prudence and skill; in fact, the system of examination was as near perfection as it was possible for anything human to be. He believed the Society had a great future before it, for division of labour was the order of the day. There was a day, not so far distant, when the apothecary and the grocer were one and the same, and a little further back, surgery and shaving were practised conjointly. These incongruous callings had now been separated, and he foresaw the time when the public would learn that a chemist and druggist with the qualification of the Pharmaceutical Society was thoroughly competent to prepare their medicines, and would rather have them prepared by such men than in the surgery of a private practitioner,—a time when medical men would be only too glad to disembarrass themselves from the irksomeness of preparing medicines, and would seek not for the profits of trade, but for a proper remuneration for skill and service rendered. He begged to name Mr. Mackay in connection with the toast.

Mr. Mackay said the Society had now existed many years, but from its formation but one object had been kept in view, viz., the advancement of pharmacy, and he need not say how well it had fulfilled its mission. He had had put into his hand a curious piece of evidence as to the wonderful change which had taken place in the prices of drugs and pharmaceutical preparations. It was an invoice, dated Feb. 23rd, 1798, sent by the Apothecaries' Company to a surgeon on board a ship lying at Sheerness, and amongst the articles supplied were 2 oz. camphor at 1s.; 4 oz. powdered ipecacuanha, 9*s*. 6*d*.; 1 lb. sugar of lead, £1; 8 oz. magnesia, 3*s*.; 2 lb. olive oil 4*s*. 8*d*., etc. with a postscript to the effect that the Company did not take back empty bottles. He was, however, glad to say that there had been a reform in prices since then. He was proud to say the Society had done a little, though, perhaps, not so much as they would have liked. In regard to the Pharmacy Act of 1852, they all knew what a goodly proportioned Bill went into Parliament, and what a miserable skeleton came out. Still, small as it was, it turned out to be a step in the right direction. Then came what had been called by some, a piece of good luck, when, in 1862, pharmaceutical chemists were exempted from serving on juries, provided they lived in England or Wales; but it was a subject for regret that in Scotland there was no exemption, simply because the operation of the Bill did not extend so far north as to cross the Tweed. He might further state that in a Bill read a second time the previous evening, and issued under the patronage of the Attorney-General that day, there was a clause exempting all registered apothecaries, medical practitioners and registered chemists from jury service. Still, even here the old fault was not amended, for Scotland was left out. This was, no doubt, owing to the proverbial modesty of Scotchmen in not advancing their claims, but he hoped the defect would be remedied before the Bill passed. He then made an allusion to the memory of the founder of the Society, Jacob Bell, thanked Dr. Greenhow for the eloquent manner in which he had proposed the toast of the evening, and expressed a hope that in the future, even more than in the past, the working of this Society would serve as a bond of union between all members of the business. He concluded by saying that had the Society done no more than put forth the efforts it had on behalf of Pharmaceutical education, and been the means of bringing together on such an occasion as the present pharmacists from so many parts of the country, it would well deserve the application of the following lines:—

> "Behold how good a thing it is,
> And how becoming well,
> Together, such as brethren are,
> In unity to dwell."

Dr. De Vry was called upon to propose the next toast, "The British Pharmaceutical Conference." He said he had watched with great interest and satisfaction the growth of the British Pharmaceutical Society; and one of its children was the Annual Conference. True, it was still but a young one; but, judging of what it had done during the last few years, and comparing the result with that of similar societies in France and Germany, which he, as a foreigner could do quite impartially, it might be congratulated upon the position it had attained; and as they had done so much already, it was only natural to expect they would go on and do much more in the future. If so much good had been done, they must all acknowledge it was in a great measure owing to the efforts of the leaders of the Society; and, therefore, he must add to the toast the name of its most able President, Mr. Brady, and its Secretary, Dr. Attfield.

Mr. Brady, in acknowledging the toast, said since he had been elected President he had had the honour of attending the sittings of an analogous body on the opposite side of the Atlantic; and with a vivid recollection in his mind of the amount of scientific work performed by the American Pharmaceutical Association, he felt just the slightest misgivings about their ensuing meeting at Brighton. He did not doubt the Pharmaceutical Conference; he never had doubted it; nor did he say they would not come out of that meeting as they had out of every previous one, able to report a certain amount of advancement to pharmacy; but he had felt a little doubtful whether they were undertaking that amount of pharmaceutical research which, as a body, they ought to. It was true that within the last four or five years there had been questions of more immediate moment pressing upon them, and that might account for the advancement of the scientific part of the programme being somewhat neglected. But now this political excitement was passed, he hoped they would give themselves to that earnest research and careful investigation of pharmaceutical problems on which alone the Conference, as distinguished from the Society, must rest its dignity and position. They must not rest on their oars if they would hold, in the estimation of Dr. De Vry and those who worked with him, the same position which he was very happy to hear they now did.

Mr. Schacht (Clifton), next proposed "The School of Pharmacy," commencing his remarks with the phrase recently used on a somewhat similar occasion by Mr. Disraeli, "Forty years ago." He said that without in any way disparaging the last generation, it might fairly be claimed for the present that some progress had been made since that time; and though many things had concurred to produce that result, some of which had been already alluded to, there could be no doubt that the main difference between the chemists of 40 years ago and the pharmacist of to-day was the superior scientific education which the latter might lay some claim to possess. This, of course, had been primarily brought about through the agency of the School of Pharmacy in London; and though it might be possible that more might be done, and that other agencies of equal potentiality might be brought into action, no one could disparage the work which that school had done, and was doing. He was always proud to think that he had been one of the earliest students of that school, and it was very gratifying to find that so many whose names had been connected with it from the commencement were still working on its behalf. It was always a great pleasure to him to look back to the time when he was a pupil of Dr. Redwood's, and he would beg to couple his name with the toast.

Dr. Redwood, in responding, said the task of proposing the toast could not have fallen into more appropriate hands; for although a large number of those present had been students in the school of pharmacy established in Bloomsbury Square some thirty years ago, he believed Mr. Schacht was the only one who represented the first fruit of the school. Since the time when Mr. Schacht entered as one of the eight or ten students who formed the laboratory class with which they commenced, he and many others, emanating from the same source, had become in different parts of the country active promulgators of pharmaceutical knowledge. These might be looked upon as so many schools dotted over the country, in which students were so well instructed that a large proportion of them were enabled to pass the required examinations without any further assistance. There was this marked difference therefore between the state of things now and thirty years ago, that while there was then only one school, there were now some hundred or more. He concluded by expressing the hope that the school of pharmacy, to which the toast referred might long prosper under the guidance of the Council of the Pharmaceutical Society, stimulated from time to time by those who, like Mr. Schacht, devoted their special attention to the promotion of pharmaceutical education.

This concluded the list of toasts, but notwithstanding that the Committee had printed a request that no other toasts should be added, there was a general feeling that the health of the President should be drunk. Mr. Savory therefore proposed the toast in a short speech, and it was drunk with acclamation. Mr. Haselden then thanked the company for the compliment. The remainder of the evening was spent in conversation, and in listening to the capital music of the Grenadier Guards' band.

The Pharmaceutical Journal.

SATURDAY, MAY 18, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE WEEK.

THE ample report which the present number contains of the various meetings in connection with the Pharmaceutical Society during the week, will explain the delay of a day which has occurred in its issue, and preclude the necessity for any lengthened reference to them here. The gathering at the Crystal Palace was all that could be desired in the way of success. Upwards of two hundred gentlemen sat down to dinner, and it was evidently the general feeling that in future years the Annual Dinner should constitute a part of the programme of the anniversary week. The wise limitation of toasting observed at the dinner, prevented a direct acknowledgment of the enthusiastic exertions of the well-known gentleman who was mainly instrumental in realizing an idea that has been for some time floating in the minds of those who are anxious to promote the well-being of pharmacists, but his services in this respect were not the less esteemed, nor will they be readily forgotten.

The Conversazione at South Kensington was well attended by about three thousand ladies and gentlemen, and this ample response to the invitations of the President and Council, not only by members of the pharmaceutical body, but also by medical and scientific men generally, is satisfactory testimony to the estimation in which the Pharmaceutical Society is held.

At the Annual Meeting, as perhaps might have been expected, the discussion turned principally upon the subject of pharmaceutical education in the provinces. The question was ably opened by Mr. ATKINSON PICKERING, of Hull, who was supported by Mr. RADLEY, of Sheffield. There was great unanimity of opinion amongst gentlemen present that something more should be done; but there was equal agreement that the subject was one of great difficulty. On the one hand, Mr. PICKERING expressed a doubt whether it would be possible to support permanently country schools of pharmacy without grants of money from the Pharmaceutical Society; on the other, Mr. MACKAY showed how much the failure of such efforts has been due to the want of interest on the part of those for whose benefit their establishment is sought.

Mr. GILES also reminded the meeting that although the Society was established to promote pharmaceutical education, it was not intended to be an educating body, the providing of education having rather become associated with it from the circumstances of the time. However great may be the temporary difficulty in dealing with this question, it is probably, as Mr. ATKINS remarked, one that will ultimately determine itself, and that most satisfactorily, when pharmacists, as a body, throughout the kingdom, are themselves thoroughly educated. This is in accordance with the President's opinion, expressed in his address, that the visit to the Society's school should be the polish which should follow scholastic duties and the ordinary instruction in the shop. Professor REDWOOD also, in his reply on behalf of the "School of Pharmacy" at the dinner, said that he looked upon the influence of the trained men leaving that school as constituting so many local schools of pharmacy dotted throughout the country.

Another subject mentioned was the cost of this Journal to the Society; and it must have been satisfactory to one who has so identified himself with its finances as Mr. JOHN MACKAY, to be able to say that the apparent deficit of £164 in the Balance-sheet represents the entire cost, including postage, of about 4000 copies that are supplied gratuitously every week.

The early closing movement was also alluded to with general approval; and we are glad to be informed that many firms intend availing themselves of the "bank holiday" next Monday, an example which we hope will next year be universally followed.

THE JURIES BILL.

ON Monday night the Government Bill for dealing with the law relating to Jury Service was read a second time. The bill is one that has been awaited for some time with considerable anxiety by the pharmaceutical body in consequence of the efforts that have been made to secure the extension of the exemption from service, hitherto limited to pharmaceutical chemists, to all chemists and druggists on the Register. It is gratifying to find that this point has been so far gained that, among the persons whom it is proposed by clause 5 of the Bill shall be "absolutely exempted from serving upon any juries "whatsoever," are "apothecaries, certificated by the "Court of Examiners of the Apothecaries' Company, "and all registered medical practitioners and *registered chemists*, if actually practising as apothecaries, medical practitioners, and registered chemists respectively."

It is with satisfaction that we are able to record the fact that the Solicitor-General has, in accordance with the suggestion of our Council, made this exemption one applying to the trade at large.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

May 15th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present,—Messrs. Atherton, Betty, Bottle, Brown, Carr, Frazer, Greenish, Groves, Hills, Mackay, Reynolds, Sandford, Savage, Shaw, Smith, Stoddart, Sutton, and Williams.

The SECRETARY presented a list of 50 members, etc., whose subscriptions had been tendered subsequently to the 30th of April.

Resolved—That they be restored to their original status upon payment respectively of a nominal fine of one shilling.

The Council considered notices of motion which had been received for the Annual General Meeting.

The business for the Annual Meeting was arranged.

The Council adjourned to the Annual Meeting.

THE THIRTY-FIRST ANNUAL GENERAL MEETING OF THE PHARMACEUTICAL SOCIETY.

Wednesday, May 15th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The Thirty-first Annual General Meeting of the Pharmaceutical Society of Great Britain was held at 17, Bloomsbury Square, on Wednesday, May, 15, 1872, at twelve o'clock.

The SECRETARY having read the notice convening the Meeting, the President delivered the following address:—

Gentlemen,—Again it is my privilege to address you at this our annual gathering, when we meet to express our opinions of the past and our wishes respecting the future,—a time when we see face to face many whom we had known only in imagination, whom we had pictured perhaps in the mind's eye from what we had heard of them or from the tenor of their writings. May all that has been good and kind in our ideal portraitures be fully realized; and if by chance there have been any stray marks of a contrary character, may they fade rapidly away,

> "Melt into thin air,
> "And like the baseless fabric of a vision,
> Leave not a rack behind."

I purpose limiting my observations to subjects which concern this Society, principally those which have been brought prominently before us during the past year. Education stands out in bold relief. The primary objects of the founders of the Pharmaceutical Society were the advancement of chemistry and pharmacy and promoting a uniform system of education of those who should practice the same, viz., the dispensers and vendors of medicines to the general public. Some may hold the opinion that the Society has not accomplished as much in this direction as they had looked for; but, turning to the pages of the 'Pharmaceutical Calendar,' and counting up some scores of names of good men and true who have taken our prizes between the years 1842 and 1872 —Robert Bentley the first upon the list, followed by many others, George F. Schacht prominent amongst them —who, some in the metropolis and some throughout the country, both by precept and example have promoted and are still promoting the cause of education, can I, can you, ignore this, and accept the opinion that our Society has accomplished so very little? That it may do more, and that the time has arrived when it should do more, is an accepted fact. With the view of promoting pharmaceutical education, lectures were given in the earliest days at the Society's House; many professors whose names are held in honour by us at first gratuitously assisted these praiseworthy endeavours. Later on, the laboratory was established for practical chemistry, and thus, so far, education was promoted; and I shall be truly sorry to see the day when the young who come from all parts of the country to Bloomsbury Square to attend lectures and work in the laboratory (the best, I believe, in the United Kingdom) are sent ruthlessly away to obtain this particular course of study where they can. But this can hardly be called the education of a youth; it is simply the polish which should follow scholastic studies and ordinary instruction in the shop. I do not and cannot look upon the Society as being in the anomalous position ascribed to it by some of acting at one and the same time as an educating and an examining body. The professors who deliver the lectures and the director of the laboratory are not members of the board of examiners, and the examiners are by no means bound to shape their questions in accordance with any special class-book, but rather upon a general acquaintance with and practical knowledge of the subject, whilst dispensing and the reading of prescriptions form no portion of the laboratory course of instruction or of the lectures delivered.

It will naturally be expected that I should not pass over the examinations without a word of comment,—substantially the Report of the Council contains all that is necessary. Experience has taught me that no examination can by any possibility please all parties, especially in the transition state through which we are at present passing; although more than three years have elapsed since the Pharmacy Act of 1868 came into force, that fact is, I think, scarcely realized by all who are interested therein. The questions for the Preliminary Examinations have been frequently adverted to by writers in the Journal, but whether they be based upon the system of teaching in use a quarter of a century ago, or upon that of the present day, the result has hitherto been the same. Although the number of failures is great, other examining boards experience similar averages. With respect to the Minor and Major examinations, I am of opinion that by no other system, and no other class of examiners, could they be more efficiently carried out; it may be found desirable after another year to make the Minor examination in chemistry a little more practical, and of which proper and timely notice would be given. I pass on now to consider briefly education in connection with provincial associations. One wish I believe pervades the whole pharmaceutic body; viz., that these associations should be encouraged, and some portion of the funds of the Society should be placed at their disposal,—the question for the future being, how shall it be carried out so as to be well done? For myself, without approaching details, I would say let it be done in a liberal spirit; let it be accomplished in such a way that those who are at present not of us, or with us, shall be constrained to join us in simple acknowledgment of the good things we have desired to do; and from the seed so sown, I shall confidently look for an abundant harvest. I remember well the old proverb, "There is that scattereth and yet increaseth, and there is that withholdeth more than is meet, and it tendeth to poverty."

The consideration of this point leads me on to another —early closing—inasmuch as "time for study" has been so frequently and persistently given as a reason for it. The advocates of early closing are in the main right. But look at it in its true light. Are two hours a day after the shop is closed the only and the proper time for study? I think not; the apprentice should virtually be studying during the hours of business, that is, he should pay attention to all that occurs in connection with his avocations during the day: not a root, bark, seed, gum, powder or liquid which comes in, should pass unnoticed at the proper time; not a process in the preparation of anything should pass unheeded if it could be conveniently attended to; and then when evening and the hour of closing come, he should devote a portion of this time to reading about those substances with which he has had to do during the day. The assistant, the skilled assistant, whose services are paid for, let him also have his share of time for keeping up his stock of knowledge. But, false modesty apart, has not the Early Closing Movement another object in view? Clearly it has, and properly so; mind and body require not only relaxation from labour, but also recreation, and for that, in moderation, time should also be given.

"Quondam citharâ tacentem
Suscitat Musam, neque semper arcum
Tendit Apollo."

There is yet another subject equally well worthy of our consideration, I mean that of prices; a theme upon which writers have constantly expatiated through the medium of our Journal. It is truly becoming a serious question that whilst the education of the pharmacist is much more costly, remuneration from a variety of causes is less satisfactory. This, like early closing, should be arranged amongst ourselves, by the requirements of the consumer and the locality; a poor man could scarcely be expected to pay after the same rate as a wealthy one, or the extreme East of London the same as the West Central. High rents, and the cost of conducting, must influence prices in different neighbourhoods; by mutual arrangement amongst ourselves, both consumers and vendors may be equally satisfied. It is a large question, too much so to be fully and fairly treated upon in this address; it is a matter upon which we cannot legislate, but upon which we may be agreed.

There is a subject I should like to mention, which has come to my notice this morning. The Juries Bill, which is before the House of Commons, has passed the second reading, and has been ordered to be printed. As it stands now, all registered chemists and druggists in England will be included in the exemption from Juries. Still, we must not raise our hopes too high, because it is quite possible that some member of the House of Commons may object to it on the third reading. Nevertheless, it is a source of congratulation.

I can refer with satisfaction to the monthly evening meetings which have been held in our lecture-hall. Upon no occasion since their commencement in October has there been any lack of subjects, and not once has the discussion flagged, but rather has been maintained beyond the ordinary time for breaking up. The attendance has been uniformly good.

The Hills Prize of books, given monthly to the candidate who passes the minor examination highest in honours, was a new feature in our report last year. It is a gratification to be able to say that a candidate has never been wanting equal to the task of gaining it, and good useful books have invariably been selected by the prizeman.

More exertion has been made on behalf of the Benevolent Fund, and already the number of subscribers from the country is in excess of last year by 138 names; the amount from all sources up to this date exceeds that received during the whole of last year. This, so far, is satisfactory, but it may be a matter for consideration whether its funded capital might not be more profitably invested and with equal security, so that independently of subscriptions a larger income might be available. Thus, whilst earnestly desiring that the demands may be few, there may be the means, when deserved, of relieving generously.

It may be observed that four members of Council have voluntarily retired this year—Messrs. G. Edwards, Groves, Reynolds, and Woolley. I cannot refrain from saying a word or two, especially of Mr. Edwards (I regret, absent this day from indisposition), who has been upon the Council continuously since the year 1847 until now; twice during that time Vice-President, also a member of the board of examiners from 1864, he has served our Society well and faithfully. During thirteen years at the Council-table I have profited by his matured experience, and I could not let him leave us without a "God speed!" and an expression of regret. Younger heads may be desirable, but Nestor and Ulysses are as requisite in the Council-chamber as Achilles and Ajax on the battle-field.

Already I feel that I have detained you too long; a word or two more and I finish.

When I first took possession of the presidential chair, I felt that I was scarcely equal to the duties, but I determined, whatever the result might be, that I would do the work cheerfully; and now, at the close of the year, I thank my fellow-councillors and our indefatigable Secretary for the assistance they have uniformly and upon all occasions afforded me, and let me repeat that the interest I have ever felt in the progress of the Pharmaceutical Society has not abated, and I trust never will be diminished.

The President then called upon the Secretary to read the Report of the Council. It was resolved that the Report be taken as read.

REPORT OF THE COUNCIL.

The Council, after a year of anxious and arduous labour, have now the satisfaction of meeting their fellow-members, and presenting the annual report. Comparing the financial statement with that of 1870, an increase of between six and seven hundred pounds will be observed in the receipts during the year from sources whence such increase might be legitimately expected, viz: from the accession of Members, Associates and Apprentices, and from the receipts for the insertion of advertisements in the Pharmaceutical Journal, and the proceeds of its sale.

It may be well to bear in mind that although the number of members may be augmented from year to year, one item of income must naturally diminish as time goes on. The entrance fees of chemists and druggists who were in business prior to the passing of the Pharmacy Act, 1868, will ultimately cease. Thenceforward, pharmaceutical chemists only, men who have passed the Major Examination, can become members. Considering, however, the great extension of the two other classes of the Society, Associates and Apprentices, which has been going on during the last two or three years, it may reasonably be hoped that a very large proportion of the rising generation will secure for themselves the highest position and title, that of Pharmaceutical Chemist—a title becoming every day better understood and more highly appreciated by the public—and having achieved that object of ambition, will naturally desire to become members of the Society, and participate in all the privileges which it can confer. Even of those who are content to rest on the Register as "Chemists and Druggists," and as "Associates" of the Society, many will probably secure for themselves the right of taking part in its proceedings by payment of the same annual subscriptions as members.

It will be observed that the fees paid by laboratory students in 1871 were not equal to those of the previous year; but there was not a corresponding falling off in the number of pupils. Many students work in the laboratory for "part time" only, probably from inability to attend the whole course. To those, however, who can devote the necessary time the Council would earnestly recommend the entire course of laboratory instruction.

The Council have during the past year paid great attention to the library; and many books carefully selected by the Committee have from month to month been added

February 2, 1872.

thereto. For the greater convenience of readers, a complete catalogue is now in preparation. In the hope that many who are closely engaged during the day would avail themselves of the opportunity of reading if the library were accessible during a part of the evening, it was arranged in January last that it should, as an experiment, be kept open on two evenings in the week from eight till ten o'clock. The total number of attendances up to April 30th was 171, and the evening average about six. The Council look forward to a larger attendance should the present early closing movement be generally responded to, and the advantages thus offered be more fully appreciated.

Under the superintendence of the Library, Museum and Laboratory, and House Committees, new cases necessary for the proper arrangement of the various specimens have been added to the museum, and in the basement of the Society's House extensive alterations have been made, by which greater convenience has been afforded to the professors and the curator for carrying on their work in connection with the museum and the Society generally.

The maintenance of correct Registers of Pharmaceutical Chemists and Chemists and Druggists must ever be a matter of great importance. It is a duty imposed on the Registrar and Council by the Pharmacy Acts. Several sections of the Act of 1868 refer exclusively to this point; and it is therein provided that the printed copy of the Register to be issued annually "shall be evidence in all courts, and before all Justices of the Peace;" consequently, copies of the Register are supplied by the Government to magistrates, coroners, and others. Cases of doubtful registration are from time to time brought before the Parliamentary Committee by the Registrar for investigation, and reported on according to their merits; whereupon, the Council, as may have been seen in the monthly reports, order the erasure of names improperly inserted. But there is a still more laborious work thrown on the Registrar. Although it is the duty of every Registrar of Deaths to send notice to Bloomsbury Square of the decease of Pharmaceutical Chemists and Chemists and Druggists which may occur in his district, many names still remain on the Register of persons who cannot be found at the addresses given; and it has therefore recently been deemed necessary to issue 1262 registered letters according to the 10th section of the Pharmacy Act, 1868, in order that the list may be freed from errors. Should the application lately made for the extended exemption from jury service be successful, a still greater necessity for accuracy will arise. The Council would urge on every chemist changing his residence to send his new address at once to the Registrar. A classified Register, according to towns, is in the course of preparation; it is found to be a work of great labour. The Council, however, trust that in a short time it will be completed.

The subject of Exemption from Service on Juries by all Registered Chemists and Druggists has been considered; and after the resolution passed by the Council in April, immediate steps to secure that exemption were taken. The Council sincerely hope that a request so reasonable and important in the interests of the public will be granted.

The granting of aid to provincial associations for facilitating the technical education of assistants and apprentices unable to avail themselves of the opportunities afforded by the Society in London, has engaged the attention of the Council. It is eminently one of considerable difficulty, requiring much careful thought, for whilst the desirability of carrying out such a project is generally admitted, it is obvious that it should be done equitably, and to be done equitably, it must be done systematically. The claims of small towns should be considered as well as those of large ones; and, indeed, at first sight, the larger would seem to require help less than the smaller.

The Council regret that the regulations which have been agreed to from time to time by the Council, on the recommendation of the Provincial Education Committee, have not worked as satisfactorily as could be desired. An alteration was agreed to by the Council at its last meeting, the effect of which will be to remove the restrictions which the Council believe have prevented the full benefit originally anticipated. The whole question, however, must be more fully gone into by the incoming Council.

The Council invite attention to the result of the examinations of the past year, as shown below. The examinations will always be a matter of the greatest interest to Pharmacists, and importance to the well-being of the Institution.

	Presented themselves.	Passed.
Major	70	50
Minor	371	234
M dified	190	123
Preliminary	1163	766

The Council having fully considered the nature of the examinations, believe them to be sufficient for the present requirements. The preliminary examination has received especial attention; and a report was published by order of the Council, by which it is hoped that all who have to undergo the ordeal will be greatly assisted.

The Council desire to draw attention to a regulation recently issued that these examinations should be held simultaneously throughout the kingdom. Representations had been made that on more than one occasion the questions propounded to the candidates at a place where the examination was held in the morning were telegraphed to another place at which the afternoon was fixed for holding it. As the questions for each examination are alike throughout the country, this irregularity is such an evident source of mischief, that it was imperative to check it. For this purpose it is now arranged that these examinations shall be everywhere held from 10 A.M. to 1 P.M. on the appointed days.

The Benevolent Fund as usual has claimed and received its share of attention; the receipts during the year are larger in amount from interest in invested property, and, at the same time, several new subscribers have been added, evincing—what is most desirable—the sympathy of the many. In order to keep it more prominently before the members, a pamphlet, setting forth the objects of the fund, rules, etc., has been published and distributed; and the subscriptions and donations are also published monthly. It is hoped that by these means the fund during this present year will be much increased.

In accordance with the expressed wish of the Society, a reporter has been in attendance at all the Council meetings of the year, taking full notes of the proceedings; and such portions as the Publication of Council Minutes Committee deemed proper have been published in the Journal; the whole being carefully preserved for reference if required at any future day by the Council. In carrying out this part of their duty, the Committee have been governed by the general interest of the members of the Society, avoiding as far as possible the publication of matter partaking more of the character of private than public business.

The Council desire to tender their hearty thanks to those gentlemen who have performed the important, and sometimes difficult, duties of Local Secretaries.

The members of the Parliamentary Committee have met regularly, considering most attentively all cases which have come before them, endeavouring without being needlessly stringent to restrict the illegal sale of poisons by unqualified persons, and protect the titles of Pharmaceutical Chemist and Chemist and Druggist.

The Petroleum Act of 1868 contained restrictions as to the keeping of petroleum that were found to be particularly oppressive and vexatious when applied to the storing of Benzol and allied preparations in small quantities; and it is satisfactory to be able to report that Clause 7 of the Petroleum Act of 1871 contains the exemptions promised to the deputation which waited on the authorities at the Home Office, and removes these restrictions. A Bill, relating to the adulteration of food and drugs, has been introduced into Parliament by Mr. Muntz, containing clauses that would be prejudicial to the interests of the pharmaceutical body. At present, its progress has been postponed, to allow of the subject being dealt with in the Government Public Health Bill. These Bills will require the careful attention of the Parliamentary Committee.

For some time past the Pharmaceutical Society has had but very insufficient accommodation for carrying on its affairs in Scotland, and more especially for conveniently and properly conducting the examinations. This fact has long been felt by the Council; and they received at their meeting, on November 1st, a letter, which was afterwards published in the Journal, from their former esteemed colleague, Mr. Henry Deane, representing that the rooms occupied by the North British Branch in Edinburgh were altogether inadequate to its requirements. After due consideration, the Council authorized Mr. Mackay, Hon. Secretary, to make inquiries with the view of obtaining premises more worthy of the Society, affording proper and sufficient accommodation for conducting the examinations, and large enough for a library and museum. The Council are pleased to be able to say that such premises have been obtained, and are now being arranged; and they believe that this will be a great benefit, not only to members, but also to associates and apprentices who go to Edinburgh to study and pass their examinations.

The Conversazione held last May at the South Kensington Museum, by permission of the Lords Commissioners of the Council of Education, afforded great gratification; and your Council have made arrangements for a similar one on the evening of the day upon which the annual meeting is held.

The Council feel pleasure in congratulating the members of the Pharmaceutical Conference on its steady increase in favour and importance, and on its "Year Book," which affords an excellent record of all important facts relating to the pharmacy of the year; and, although officially unconnected with the Pharmaceutical Society, there can be no doubt that the two bodies should be in strict unison, as their objects are similar, and most of the active spirits of the Conference belong also to the Society.

In the sad disaster which befell Chicago, the College of Pharmacy there established was destroyed. It is gratifying to reflect that the pharmacists of England were reckoned upon—and not in vain—to assist their unfortunate fellow-labourers; the appeal has been well responded to, in contributions both of books and money.

The emphatic condemnation of compulsory "Poison Regulations" by a very large majority of the trade, and the active steps taken by your Council and others to give weight and effect to the voice of the country in reference thereto, produced the desired result, and induced the Government to withdraw their Bill for imposing upon chemists and druggists further restrictious in the keeping and sale of poisons. This projected measure was an object of frequent and anxious deliberation with your Council, who cannot close this Report without expressing their feeling of satisfaction that the excitement and antagonism of the first few weeks of their official existence steadily and speedily disappeared on the withdrawal of Mr. Foster's Bill which had provoked it, leaving them to pursue uninterruptedly the business, and they hope, advance the true interests of the Society.

The following registers were placed before the meeting:—

Register of Members, Associates and Apprentices of the Society.
Register of Pharmaceutical Chemists.
Register of Assistants.
Register of Apprentices or Students.
Under the Pharmacy Act, 1852.
Register of Chemists and Druggists.
Under the Pharmacy Act, 1868.

Mr. Wilkinson (Manchester) said: Mr. Chairman and gentlemen, I have the honour of being asked this morning to move the adoption of the Report, and I wish that it had fallen into abler hands. I have come here quite unprepared to do anything of the kind. I will not call your attention to the various paragraphs of the Report, because I think there are a good many gentlemen here who have got something to say upon some of them; at all events I do not wish to take it out of their hands. I find that the finances are in a very satisfactory condition; that we have a balance in the treasurer's hands of £700. I find the Benevolent Fund is also in a satisfactory condition. The first paragraph is very satisfactory; that we have received from various sources £600 or £700 more than we received last year, and we hope that such a course will continue. I leave it to gentlemen who are prepared to speak upon the subject, and simply move,

"That the Report of the Council now read be received and adopted, and printed in the Journal and Transactions of the Society."

Mr. Atkins (Salisbury): Mr. Chairman and gentlemen, I rise to second the motion. I can say with Mr. Wilkinson that I am entirely unprepared to speak upon this occasion, having only just been requested to second the adoption of the Report. I, however, can say that I do so with a very great deal of pleasure. I think the Report, whatever exceptions may be taken to parts, —I have no exception myself to take to it—is an admirable one, and should be a source of entire and deep satisfaction to us who take an interest in the well-being of pharmacy. There are gentlemen who, no doubt, will speak upon points which they have made specially their study, and I will only say one word with regard to a topic upon which I have been making some investigation, namely, the question of provincial education, or rather apprenticeship. However admirable the work which the Society is doing, and it is doing a very great work, and doing it well, I cannot say I that think the figures in respect to the examinations are at all satisfactory. I think that the failures in the Preliminary examinations are a source of very considerable anxiety. It is a source I may say of very considerable depression to those who unfortunately attempting the ordeal fail, and to those who are parents and guardians of such as do fail. I think it would be most unwise on our part as a body to relax or lower the standard of Preliminary Examinations, but I must be allowed to repeat now that which I have written—the absolute importance of the Preliminary examinations or their equivalents being passed before apprenticeship commences. I hold it is not our duty; we are not called upon to investigate, to instruct, to analyse the results of a classical or liberal education; and surely the Preliminary examination is placed I may say so low, that we cannot speak of the education as a liberal one or a classical one which fails to pass that limit. Provincial education is a great subject. I was struck, Sir, with the discretion, prudence and thoughtfulness of your own remarks. They quite echo my own feelings. Something, doubtless, will be done, and no doubt by the incoming Council it will be maturely considered. However, I cannot but feel the force of another remark you made, that we are now passing through a transition period. The question of provincial education will ultimately determine itself, and that most satisfactorily when we, as a body, throughout the kingdom, are ourselves thoroughly educated. I do not refer for one moment to a liberal or classical education, but I refer to technical education. No doubt, when the coming generation has become a thoroughly educated body, we shall be perfectly able to take care of the interests of our apprentices. But until that is done, there is a work indeed to be done by associated effort, and I hope the Council will give that matter their very grave consideration. I feel very deeply indeed the present position of our apprentices. I think it must be a very great regret that you find in provincial towns five or six or even more apprentices who have not passed the Preliminary examinations who are just going out of their time as assistants. There are absolutely assistants upon assistants in our provincial towns who have not passed that examination. I say they are only piling up difficulty upon difficulty, and there must be a weeding-out process by-and-by. I have great pleasure in seconding the adoption of the Report.

Mr. Atkinson Pickering (Hull): Mr. Chairman and Gentlemen,—This is the first time I have had the pleasure of attending the Annual Meeting of the Society, and I wish to put before the members of the Council the wants and the necessities of the country members. With very much that has fallen from you, Sir, I agree, but not altogether. You gave us in your own words the first paragraph of the charter of incorporation which was granted to the Pharmaceutical Society, and you stated it was granted for the purpose of promoting chemistry and pharmacy, and also for promoting a universal system of education of the members of the trade which practised that calling. I regret exceedingly to find that after the lapse of about thirty years no general system of education has been inaugurated by the Council of the Pharmaceutical Society. I do not come here to speak one disrespectful word of any of the members of the present or past Councils. We owe to them a great deal of gratitude for the time which they have devoted to the interests of the trade. I come not here to find fault with the Institution in which we are now assembled. The country members are quite as proud of it as their town brethren. But at the same time I cannot shut my eyes to the fact that as an educating institution it affords to our country apprentices and assistants but very little help. I do not altogether agree with the remark which has been made with regard to the education and with regard to the assistance which the apprentices should receive from their employers. I think it is exceedingly desirable that provincial schools of pharmacy should be established in a number of large towns, and that these schools, to make them permanent, should be assisted by grants of money from the funds of the Pharmaceutical Society. There is now a considerable surplus income, and I do not think it desirable that that surplus year by year should be invested in Consols when the great mass of the apprentices and assistants in the country need that money to be expended in promoting their advancement and education. It has been a source of regret to me that the resolutions adopted by the Council of the Pharmaceutical Society upon that subject have been attended with so little result. I attribute that smallness of result to the resolutions themselves, to grant small sums of money for the purchase of specimens of chemicals, of specimens of materia medica, or for the purpose of forming a library, which are all very well in themselves, but that is little or nothing towards what we require in the country. We do not presume to found schools of pharmacy on so broad and extensive a basis as this one in Bloomsbury Square, but the school of pharmacy which we are anxious to establish is one where lectures on chemistry, materia medica and botany shall be given, so that our apprentices and our assistants may have nothing at all to do but to come up to this institution and pass their examinations without being put to the expense of attending for six months the laboratories and lectures here. We cannot doubt the fact that the great majority of those who are apprenticed to the trade in the country are sons of people not altogether in humble circumstances, but of very moderate means. There are many apprentices in the country whose friends could not afford to send them up to London for six months to attend a course of lectures here. How are these youths to be educated? They come up and they pay a premium. The premium which they pay to the great majority of country chemists does not provide them with board and lodging. The greater portion of every day must be devoted to labour in connection with their own business. They get an abundant practical knowledge during their apprenticeship, quite as good and practical a knowledge as they can in any establishment in London. What they require in the country is scientific training, and that scientific training will be best given by lecturers who are well up in the subjects upon which they are called to lecture. I do not mean to say that we may not be able to establish a school of pharmacy in the country; but I have great doubt indeed in my own mind as to whether it can be supported permanently without grants of money from the parent Society in London. I should wish to see these schools of pharmacy on a firm and satisfactory basis, affiliated with the parent Society in London; and I should also wish that the Council, before they made grants, should be satisfied that the money is going to be expended in a satisfactory manner. I trust that during the coming year the Council of the Society will give this subject their most serious attention. Two years ago the subject was very ably brought before the members at the annual meeting by Mr. Schacht, and I regret to find that we are as far as ever from having that subject carried out. There does not seem to me, judging from the report which I have read, to be really any scheme adopted for assisting provincial education; because to lend a few apparatus for fourteen days is perfectly useless to us. I do not mean to say but that there may be some expensive apparatus for an experiment or two which might be of service; but that is not educating. The country members of the trade are quite prepared to furnish their own school of pharmacy with apparatus; they are quite prepared to provide their own library, to take their fair share of the expenses of this school of pharmacy. But they consider they are entitled to a fair share of the income of the parent Society to which they have so long contributed, and from which hitherto they have received comparatively little in return. We do not wish to undervalue the Journal which we receive every week, because it is very creditable to the Society; but at the same time it does not afford us that assistance which we require. Neither does it furnish us with the means of educating our apprentices or assistants in a satisfactory manner. After a man has devoted ten or twelve hours a day to business, it can scarcely be expected that he will devote two or three hours of an evening, which is the only time he has for social comfort in his own family, to instruct youths in the scientific portion of their business; he may afford to them time for reading, and we do that in Hull. I am glad to say that the great majority of the trade now close their places of business at eight o'clock. I have always done so since I have been in business. I stood behind a counter from seven o'clock in the morning until half-past eleven o'clock at night for two years and a half; and when I tell you that at the end of that time with a heavy coat on I did not weigh seven stone, I need not say more to show the injurious effect which those long hours had upon myself. For twelve months after I left, I was utterly incapable of doing anything in the shape of work; and I should be very sorry if I thought any young man of mine ever passed through such an ordeal as I did myself. I rejoice to tell the gentlemen here present that early closing has found a ready response in Hull; and whilst some members of the trade have not thus far seen their own interest to discontinue it, I trust that they will, and that the claims which their wives and children have upon them will be found greater than the claims of their pockets. There is another subject in the Report which I rather regret. A great deal has been said about the Benevolent Fund. Those who hear me—and there are members of my own trade here who know me well—will feel sure that I am the last man who would wish to say one word in disparagement of that fund. At the same time I quite agree that it is time the Benevolent Fund and the funds of the Society were placed in different investments. If any of us have any money—and it is a trade where very few can make money—we are very anxious to get as near 5 per cent. for it as we can. We are glad to have a little to help us to a crust of bread and a drink of water in our old age, and it is necessary to have our money so invested as to bring us in as large an income as possible. I think there have been times when the Benevolent Fund might have been invested so as to bring four and a half per cent. Do our large insurance offices invest their funds in Consols? Only until they get a better investment. I think the funds of the Society would be far better invested in another way.

Our worthy friend, Mr. Hills, who granted us money for prizes, did not invest his money in that way. Russian Five per Cents. during the Crimean War occupied a better position than our own Consols; they went down less in the Money Market. I should like to see the funds of the Society and of the Benevolent Fund differently invested. I am a plain Yorkshireman, and I have come here to speak my mind; and if I don't speak it in courteous language, the truth is, I live so far distant from Court. It is only occasionally we have the honour and pleasure of seeing our Sovereign and beloved Queen, and when we do there are no people under heaven who are more willing to render her the respect which is due to so excellent a woman than Yorkshiremen. With these remarks I am quite willing to leave the subject of Pharmaceutical Education in the hands of the incoming Council; and I trust it will receive from them such a consideration as will result in some permanent system being adopted for the permanent assistance of our provincial schools of pharmacy. We do not expect to found anything of a kind equal to the Society here in London; but when I tell you that in our present botany classes we have twenty-six students, the great majority of whom are members of the trade, I think I have given a substantial reason why we are entitled. I think it is no very bad beginning for a provincial school that twenty-six should be found willing to join its botany classses. I trust I have said something that will induce the members of the Council to give us a grant of money, for it is money that we want.

Mr. Wheeler (London): I should like to ask the previous speaker how many provincial schools he wishes to establish, and how are the outlying towns to be provided for? Are the large towns only, such as Hull, Sheffield, Liverpool, Manchester and Brighton, to be provided with provincial schools, and the small towns left unprovided for?

Mr. Pickering: I may say that we are anxious in Hull to make our school the focus of the neighbourhood; to establish lectures at such hours of the day as will enable those who reside in the smaller towns around us to attend those lectures. I myself saw a member of the society at Beverley, and endeavoured to induce him to provide means, so that a number of young men might drive over to our lectures in Hull, and avail themselves of them. I can only say that we are quite as anxious in behalf of the apprentices and assistants of the smaller towns surrounding us as we are for ourselves.

Mr. Radley (Sheffield): Sir, I have taken a great interest in the subject of provincial education, and I feel exceedingly obliged to Mr. Pickering for the very lucid manner in which he has described the requirements, opinions and feelings of the country members of this Association. In reference to the outlying small places, I have no doubt that some arrangement might be made in other places as at Sheffield. The Midland Company have offered to charge one fare from various towns in connection with our association, and I have no doubt that the same thing will take place in other parts of the country. With respect to the amount of assistance required, for my own part, I think it will be a difficult matter for this Society to undertake to form and sustain completely these country associations. Any assistance must be supplementary to a large amount of local effort. Already in various centres a large amount of money has been expended by members of various associations; and with a little encouragement from the parent Society, I am persuaded that they will still continue their efforts. It is not, as has been supposed, to give a premium to idleness on the part of these young men that we ask for money, but it is to support and assist those who are in earnest in the matter. I feel quite sure that a good feeling throughout the country will be promoted. There are persons in Sheffield who have held aloof from this Society entirely on the ground of what they have supposed to be a want of sympathy with the country associations shown by the London Society. In reference to the remark respecting the failures in the Preliminary examination, I think there is a remedy; for I find that the youths who are just coming from school, and are about entering the business, for the most part pass the examinations readily. It is those persons who have not been favoured with a generous education, and who have arrived at something like years of maturity, who fail. No doubt after a few years the number of failures will be comparatively small. Perhaps I may be allowed to make one or two remarks in reference to the Report and some other matters. I notice the statement in the Report with reference to the Journal, and it appears to cost the Society about £1000 a year. I think it is scarcely right that such a large sum of money should be disposed of in one way. It strikes me it would be desirable to have a more full and particular account. As an old member, one of the founders of the Pharmaceutical Society, I feel exceedingly gratified to find that, after all expenses have been met during the past year, there is a balance of nearly £1700 in hand. I notice that during the past two years there has been an expenditure for repairs and alterations to a very large amount. For two years the furniture, fixtures, fittings, repairs, etc., are £1368. I hope that there will be less outlay under those heads, and the funds available for educational purposes will be larger than they are. It is a matter of very great satisfaction to my own mind to find that upon the whole, the affairs of the Society are so prosperous; and I feel quite sure that any little movement that has been set on foot with reference to country education will receive a further impetus.

Mr. Mackay (Edinburgh): Allow me to say with reference to the Journal account that the balance up to Dec. 31st is represented by £164. 9*s*. 7*d*. I may mention that at the time our Journal ceased to be a monthly publication and became converted into a weekly one, it was a matter of considerable anxiety, and various calculations were made by the Council and Committee: first of all to see whether it would be desirable to change our publication from a monthly to a weekly form; and very many calculations were gone into as to whether it would please those who were interested to get a weekly publication, and if so resolved, what would be the financial position of matters. It was agreed then that very probably there might be a balance against the Society of £300, £400, or £500 at the end of the year. Notwithstanding that probable balance, it was felt that it would be a desirable thing, at all events, to make the experiment. As we all know, the change was made, and it has resulted in this, that the balance last year is less than we estimated, being only, as I have said, £164. I do not wish the gentleman who has just spoken to entertain the idea that this is a mere haphazard sum. The Secretary has gone into the whole matter, and at our Council meetings there is published a regular statement, which is headed "Journal Account," in which all matters are given, commencing with editor's salary, sub-editor's, contributors, and so on. I take it this is quite open to any member of the Society to look at; and if this meeting should so determine, I do not see any reason why the whole statement should not be printed along with next year's expenditure. But, I would press upon the meeting that the Council have not been at all careless in carrying out this Journal account. Bearing in mind the enormous weekly gratuitous circulation, equal to about 4,000 copies, the result is as I have already stated. Now, I desire to make one or two remarks upon the very vexed question of provincial education. I am delighted beyond expression that we are at one mind in this respect—that there is no difference of opinion whatever in regard to the fact, that money must be given from the parent Society to assist some of the provincial associations; but, whilst I say that, I call it a vexed question, I repeat that the proper manner of bestowing these grants is one of extreme difficulty. I have listened with great interest to the remarks which have been made by the gentlemen who have spoken, and I have read from time to time the various proposals which have been made, and I confess that I am almost in a kind of mist, and do not at the present time see my way out of the surrounding darkness; but I take it that this our Annual Meeting is one of the very best possible opportunities for opening up a path, the using of which may not only be easy, but afford pleasure and satisfaction to the next Council. I therefore take it that no positive action of any kind in connection with this subject can be taken here to-day. But we have gentlemen present who, no doubt, will do what they can, to assist those who are about to take up the affairs of the Society for another year. A great deal has been said about founding provincial schools. The claims of this Society, I need not for one moment advance in a meeting such as the present. But, turning to the Journal of May 4th, 1872, I find that in Leeds it is stated that there are in business there 112 gentlemen. Of these 112 in Leeds, there are connected with the Society 27; of associates not in business and registered apprentices, 11. We have had a sound, and not an uncertain one, from the enterprising town of Sheffield, and there I find the total number in business 100; connected with the Society, 27; associates not in business and registered apprentices, 9. I go again to Hull, the claims of which have been so ably stated by Mr. Pickering, and I find there the total number in business 102; connected with the Society 19; associates not in business and registered apprentices, 4.

Mr. Pickering: I think there is a mistake there. We have only 90 in the trade.

Mr. Mackay: As this was never contradicted, I took it for granted it was admitted as correct; but I will read it as 90.* Now this is a state of matters which I think should not be. I hope the time has passed when it will be possible for such a table to be again printed. But in connection with this statement, I cannot but feel that while the young men may have been to blame, and are to blame, there is an amount of blame attachable to the masters, to which I not only take this opportunity of drawing attention, but which I would ask them to look fairly in the face. After the passing of the Pharmacy Act of 1852, we had a visit from the late respected and venerated Jacob Bell, in Edinburgh. In 1853, at a meeting there I made a motion to the effect that, now that the Pharmacy Act was passed, small as the privileges were which it gave, masters—chemists and druggists—in taking apprentices should put in a clause in the indentures binding each youth to attend a course of lectures on materia medica and chemistry. That was seconded and carried. Observe; at that time there was no such thing as Preliminary examination. Mr. Bell made a second motion to the effect that practical chemistry and botany should be added wherever it could be done. Those two motions were passed; and they have been to a certain extent acted upon. For myself, I have always acted upon it; and, in addition, since the Preliminary examination has come into operation, I am safe in saying that I am joined by a good many, not only in Edinburgh, but out of it, who, when a parent or guardian makes an inquiry as to a vacancy in an establishment, the very first thing said is—if there is a vacancy—A. B. will be taken, but not until he has passed the Preliminary examination of the Society. Then the next point is—that being agreed—if your son, after a month's trial pleases, and likes the business, a clause shall be inserted in the indentures by which C. D., as a master, binds himself to give time to the pupil, A. B., to attend a course of materia medica, chemistry, and botany, you finding the money, C. D., as I have said, giving the time. The effect of such an arrangement is, that during the apprenticeship, a full course of these three scientific departments is made available; and if the youth during the five years' apprenticeship takes advantage of the collection of specimens to which he ought to be admitted, and occupies his spare time in reading, the great probability is that, at the end of his apprenticeship, with perhaps a course of three months' practical chemistry, or even one months' close study, he may with some degree of credit pass his Minor examination. I say again, in drawing the attention of gentlemen now present to this, that if they would follow out such plan, I believe the rejections which we see with so much regret would not be so numerous. I am quite aware I am advocating a system as to which it may be said,—That is all very well for you in Edinburgh and Glasgow, London, Liverpool, or Brighton and other large towns, but such a course could not be carried out in the small villages. It is that very fact which prevents me from seeing my way as an individual in regard to the proposed grants for education in the country. I repeat that is the very reason why I fail to see any manner in which we can justly draft to certain large towns a considerable sum of money for the purpose of founding provincial schools of pharmacy. I know it may be said—why should you refuse to establish provincial schools of pharmacy all over the country? Why should you allow pupils in London to get for one guinea what it costs us in the country three or four guineas to obtain? What is the reply? I myself would not object to see our present professors cease to get their £300 a year from the funds of this Society. Some gentlemen will be horrified at hearing me say that. But I have the conviction, and as an honest man I speak it. Turning to the annual account now on the table, I find that for years we have paid £600 a year to two lecturers, and the fees set off against the £600 come to £189, leaving a sum of £411, which you hand over to these gentlemen. I say the labourer is well worthy of his hire, and I should not wish for a single moment to see the professors paid less. My desire is to see them get more. But the question comes, in what way? I say, as a Pharmaceutical Society, we should certainly have the power to appoint our own professors, and I have no hesitation in saying that the Council of this Society should appoint Professor Redwood and give him the use of the lecture room and apparatus in our present house, and so I say with regard to Professor Bentley. But do not let these salaries be paid at the expense of parties in country towns who never will be able to take advantage of the lectures. Let the student come here and pay a legitimate price for the lectures. I venture to say from what I know of the character of the lectures given in this hall, that there is no young man who would grudge a minimum sum, say of three guineas. If that be the case, taking the numbers attending at 73 and 60, as I find them to be during the present session; and it is not at all beyond our imagination to suppose that these 73 and 60 may be increased by 20 or 30 in both cases; if, therefore, you have three guineas instead of one guinea for each ticket, your professors would then be paid more than £300 a year, and right welcome, would they be to it. It will, therefore, be apparent that I am opposed to the idea of giving large sums of money to provincial centres for the purpose of founding or endowing professorial or educational chairs. I would even go to the laboratory, and say if you appoint Professor Attfield, and give him the use of the laboratory upstairs he would, by charging his own fees, make a larger income than he at present derives, while the funds of the Society would also be benefited. I say it is the duty of the Society to do what it can to assist not only *large* provincial centres, but *small* provincial centres. But then I come to the difficulty—how is that to be accomplished? Although it has been cast aside by Mr. Pickering, I think if this

* There are 97 names given in Kelly's Post Office Directory of Chemists and Druggists; besides these there are four pharmaceutical chemists whose names are not included therein, and one associate in business.—Ed. Pharm. Journ.

Society were to establish in many places a museum, a library, rooms for meeting and even apparatus for the use of the lecturer, that would be doing great good, but I would not make these little circles surround only those who are connected with the Society. We must never forget that the young pharmacist is, after all, the individual who is to foster and increase the position of the Society; and as there must be a term and course of study for these young men, I would be disposed to suggest that under some surveillance, such as that of the local secretary or committee, the privilege of free rooms, library, use of apparatus, and so on, might be given; but let the lecturer be paid proper fees by those pupils who attended. Thus, I think that by admitting all who are studying pharmacy this Society would be doing legitimately its business. Even if you were to send down to some of these provincial centres comparatively large sums of money, and give a gentleman a lecture-room as large as this, with all its appliances, and open the door and say to the young men, Come in to the lecture, my conviction is that such gratuitous system would not draw a class; and the reason I say so is, I think, capable of proof, and is borne out very much from what my friend, Mr. Shaw, of Liverpool, stated at a very recent meeting of the Council. He said, "But although there must be from three hundred to four hundred apprentices and assistants in the town of Liverpool, these lectures have not been attended by more than half-a-dozen, while the materia medica lectures were attended by two only." Then Mr. Stoddart, from Bristol, said, "This showed we ought to be rather circumspect in this matter, and see that people tried their best to help themselves before asking assistance." Then, passing on from Bristol, we come to that most important of all the north of England towns—Newcastle; Mr. Brady states, "But where are the eight or nine, (not eighty or ninety)? I have heard more than once of a class not being held because only one or two came to it." I now go to Norwich, and there I find it stated that the attendance has been very limited. Then I go on, and come to that most important of all manufacturing towns, Bradford. I find there that our friends, Messrs. Remington and Bell, have issued a circular in which they state, "The Council of this Society feel it to be a matter for deep regret that the lectures it instituted about three years ago should be discontinued for want of support by those they were intended to benefit." I think I need read no more to give a clue to what has caused me to come to the conviction that at the present time, at all events, it is not right for any Council of this Society to make large grants of money to gentlemen who are willing and able to teach. What may be the result of this day's meeting we cannot tell. I am sure you, Sir, as well as the other gentlemen in this hall, will be delighted to hear any suggestion, and I am equally certain that those gentlemen who are about to come on the new Council will pay due respect to what may be said, because we all want, to a certain extent, information upon this important subject.

Mr. Humpage (London): Mr. Chairman and gentlemen,—As a very old member of this Society, I feel at liberty to stand up and say a few words, and what I shall say will be quite of a practical character. I must say that when this school of pharmacy was established, thirty years ago, it was to meet to a great extent a want, one which I had experienced ten or fifteen years previously. Having had an education in the country, my good father, as he thought, placed me with one of the first houses in the country, where he thought I should get a scientific education. I learnt well how to wrap Windsor soap, and after a time, Epsom salts. I went to this establishment two months on trial; and having been two years previously with my father, I was anxious to know what I was to learn; and as there were four or five apprentices there and one or two assistants, I looked about, opened my eyes, made inquiries, and I found that young men whose parents had paid 250 guineas as a premium were leaving that establishment literally knowing nothing. I said,—This won't do: my father has sent me here under the impression that I could be made a chemist of; and if I go back knowing no more than these, I shall be boxed on the ears, or something worse. I therefore at once wrote to my father. He said, "Do as you like; I leave it with you." I then took the earliest opportunity, in a very respectful manner, of saying that I had been deceived; that I had come to that institution under such and such an impression, and I found those were erroneous. The gentleman behaved like a gentleman. He said, "I did not represent you would be made a chemist of; your friends might." I said, "Well, my father has left it to me, and yesterday I was thoroughly decided by this fact. Your senior apprentice came to me and asked me a question so ignorantly that I was disgusted." I left; but I did the wrong thing in leaving, because I tumbled into another place not half so respectable, and the result was that at the end of my three years I came out little better than I went in. My father came up to London with me; he was very anxious about me. He found there was no vacancy at such places as Bell's or Allen's, and I dropped into another position, but found nothing there. When, therefore, I found a move was made to found a school where a young man whose parents were willing to pay for him could get an education which he could not obtain during his apprenticeship, and when this institution was established, I felt it was the want of the trade. What did it propose to do? Not to grant money to provincial establishments. I say that now this school is established, with eminent professors, a good laboratory, lectures, and every appliance, it is absurd to think we can get anything like it elsewhere. It has been said very justly that it is not every young man who can come to London. Admitted. But I say if a young man has served his apprenticeship in the country and he wishes to come and attend these lectures, he can come. The last five young men whom I have had the pleasure of residing with me did come from the country, and, with but one exception, they have passed the Minor examination, and two of them passed in honours. Yet they did not come up from the country with any large amount, but they were determined to help themselves. They did not ask, "How many nights can I go out, Sir?" but "I want to attend the Society." They were made of the right sort of stuff; and I say if a young man wants so much time to himself he has no right to ask for a full salary. Too many want the pudding without paying for it. I say, with a clear perception of the facts, that those young men who are panting for knowledge in the country can get it. Let there be a meeting-room or anything of the sort in the country; but let the young man come to London who knows his Pharmacopœia fairly, and he has no difficulty if he will enter into an arrangement with a chemist in, or two or three miles from, London. I would not give the evenings, but let them have the mornings; that is the time,—say from nine till one. Let them attend the Society's lectures, examine the preparations they make, make whatever inquiries they can, and I declare there is no difficulty at all for these chemists and druggists from the country passing their examinations and being a credit to this Society. The provincial friends can assist its being done. Let the young men barter for time. I should not like them to work and slave as Mr. Pickering did, till he was diminished, he said, even in his very growth. A young man with the right stuff in him need not fear getting a situation. Let young men do all they can for themselves, and this Society I am sure will help them. How can schools be established in the country? You cannot make a grant to the large towns, and leave the small towns vacant. It is no use talking about the Midland Company bringing them at half fare; it would cost double what it would to come to London, where we have this Institution and all its appliances. I say there is no difficulty in the matter, and I am sure the body of men we shall have in a few years will be a credit to us.

Mr. Clarke: Mr. Chairman and Gentlemen,—I desire to trouble the meeting with a few words; because, whilst the facts which Mr. Mackay has stated with regard to provincial schools are decidedly true, there is something to be heard on the other side. I can give some information with regard to Leicester. We formed an association for assistants and apprentices there, and for the last two or three years the increase has been steady; the average is from fourteen to fifteen every evening, which I think remarkably good considering that in the whole town there are not more than from forty-five to fifty. Thirty out of the whole fifty have joined the society. Again, at least as many young men as we could expect in such a town have passed the examinations of the Pharmaceutical Society, including both the Preliminary and Major. And I take this opportunity of referring to a fact which shows the very bad working of the regulations with regard to grants to provincial associations. The Leicester Association had the pleasure of receiving a loan of £10 from the parent Society, but its reception was attended with far more trouble than it was worth. A great part of the money was expended in books, but such a number of letters had to be written to our esteemed Secretary that it caused so much annoyance that it was generally voted a nuisance. Now it is very evident that if the Pharmaceutical Society finds the money for the provincial grants, it should be spent in the very best way possible. None of us would like to see some works or materials bought by one association at 25 per cent. less than was paid by another. The books purchased by the Leicester Association were bought at the published prices, less 25 per cent. discount; but the mother association out of a similar grant has paid the full price for the books. Such facts ought not to exist, and I thought it perhaps might do good to mention them.

Mr. Berdoe (London): Sir,—I cannot allow this discussion on provincial education to pass without uttering my protest, feeble though it be, against a great deal of the language I see used about the work apprentices and assistants are compelled to do. I constantly hear and read that the opening of the shop, sweeping out and cleaning it and so forth, are derogatory to the position of persons in a pharmaceutical establishment. But I maintain that the work necessary to be done in a chemist's shop is really of the most essential importance to the acquirement of business habits, carefulness, and scrupulous neatness and tidiness. I cannot tell you how indignant I feel when I read letters in the Journal from young men who complain that they are kept rolling pills and stirring ointments, and doing those thousand-and-one things necessary to be done. I am certain that the spirit which those remarks calls forth is very detrimental to the best interests of the young men themselves. I hope you will not consider me egotistic if I just refer to my own career. I was apprenticed in the country with one of the founders of the Society, and in about two or three months my emyloyer said I had better connect myself with the Pharmaceutical Society at once. My master did not liberate me from opening shop at the proper time and doing the necessary amount of brass cleaning and so forth. But he encouraged me to get up very early in the morning, go out botanizing, and when the shop was shut he was very much annoyed if he saw me reading anything but scientific books. I may say here that I never found cleaning windows, cleaning brass plates, or washing bottles interfere with scientific education; in fact, I rather think one assists the other, and incline to the belief expressed in Dotheboy's Hall, that you may learn botany whilst weeding a garden. I used to get up early in the morning, and succeeded ultimately in passing examination as a pharmaceutical chemist. Therefore, I say that I totally object to the remarks which I constantly see with reference to that subject; and if young men desire scientific education, they can get it without putting the Society to the expense of establishing in every little village a school of pharmacy.

Mr. Schacht: Sir,—At the risk of being thought somewhat intrusive upon this subject, I shall venture to say a word or two, as one seems to be a little challenged to suggest something for the consideration of the next Council in the way of a practical solution of the difficulty, which so clear a head as Mr. Mackay's fails to see a way out of. It is a matter to me of excessive pleasure to find how general appears to be the feeling that this Society should do more than it has hitherto done for the cause of provincial education; and I desire to elicit something like a general opinion upon the subject for the guidance of those who are to have the future conduct of the Society. The first thing to be made clear in one's own mind is the general principle that should guide the Society in the education of its members, and around which should ultimately group all its efforts. I would rather that there were no such question as provincial pharmaceutical education; but, inasmuch as it is a subject which has received a certain amount of practical elucidation at the hands of this Society, we must deal with it. The difficulty which seems to strike most of those who have thought upon the matter is, that whereas it seems to be granted on the one hand that the provinces have a perfect right to receive money aid from this Society; on the other hand, it is seen that those who have the management of the funds of this Society should exercise the greatest care that none of it should be misapplied. Therefore it is that we hear these very natural suggestions as to the difficulty of establishing and maintaining provincial schools, inasmuch as it appears to be somewhat unjust, when you are seeking for an abstract principle to guide you, that Liverpool, Bristol, Hull, and a few other great centres only should be blessed with the privileges and advantages which we are striving to obtain out of the funds of the Society. Therefore, one seeks for some sort of plan which shall not be open, at any rate, to that worst of all possible charges—injustice. I can find but one solution, and that is a system which should simply grant aid for results; nothing in anticipation of what may be done, but as an acknowledgment of what has been bone. It occurs to me that such a plan as that we have cut and dried for our adoption. It is the system adopted by the Government for aiding scientific education. I have been bold sometimes in expressing my views upon this subject. I find that I have been misunderstood amongst my friends. My notion is not to do anything hastily, but adopt a plan which shall ultimately obtain throughout. But, in the meantime, I would not touch the processes which are going on in this school for a moment. It has worked good things in the past, and let us hope it will continue to do so. It would be a great pity to disturb all that is systematized in this establishment; but if we can get a system which shall simply pay for results, and it is found to work well, we can gradually bring this establishment into precisely the same system. It is scarcely necessary; it would be unwise to go into details; but any system adopted should be one that would foster the establishment of provincial schools by local effort, by some process similar to that adopted by the Science and Art Department of the State. Examinations should be yearly held in the three branches, materia medica, chemistry, and botany, or perhaps only two. All provincial schools should be recognized, and required to have a systematized process of teaching; and all those who passed should earn for the establishments in which they passed certain grants of money, to be handed over to the schools, and applied according to the wisdom of those who had instituted the schools. It should be given without grudge, without stint, and without control, because those who had the courage and generosity to establish the schools could surely be trusted with this small portion of their own money, as it were, back again. That would encourage local effort to a very great extent; and, as it seems to me, encourage effort on the part of the students, who would desire to bring back to the schools some portion of the money expended upon them. And those who had the administration of the funds of the Society would feel that not one single penny given was being misapplied, inasmuch as it would all have been fairly earned. Again, it would serve to enlist the sympathy of the whole trade in the well-doing of the Society. Every one would feel he was repaying a positive money reward from his association with the institution. I have just said this in order to elicit the views of those now assembled.

Mr. Vizer (London): I have listened with great pleasure to the observations made by our friends this morning. They have thoroughly ventilated the subject of Provincial Education, and I am sincerely glad to see that there seems to be so general a feeling in favour of the Society's extending its efforts in that direction. With regard to the Report, I will ask permission to make a remark or two on the second paragraph, which contains two very important points. The first is—a fact stated—that "the entrance fees of chemists and druggists who were in business previous to the passing of the Pharmacy Act, 1868, will ultimately cease." The other is,—a hope expressed—"that a large proportion of the rising generation will secure for themselves the highest position and title, that of Pharmaceutical Chemist, a title becoming every day better understood and more highly appreciated by the public; and, having achieved that object of ambition, will naturally desire to become members of the Society." These are two very important points; and as one who sincerely desires the welfare of this Society, I venture to make one or two observations upon them. Facts are stubborn things, and we have here the fact plainly stated, that the entrance fees of chemists and druggists must ultimately cease. Now the question suggests itself, what are we gaining by those fees? During the year we have received £222 for entrance fees of this kind, representing 106 outsiders who have sought membership. Now, I must confess, and I have said the same before, that I do think it would be for the benefit of this Society if we could by any means get rid of that entrance fee. We have got £222 in cash, and with it £106 per annum; the question is, whether, if that two-guinea fee were abolished, many persons who now remain outside the Society would not come in. I am aware that theory says why should we admit these persons who have never done anything for the benefit of the Society without making them pay something for the privilege? Now theory is very good, but it often has to give way to practical experience, and I think this is a case in point. If we could only get rid of this two-guinea entrance fee, it is my firm opinion, many would be inclined to join our Society; and instead of having £222 to invest at three per cent., you would get some hundreds of pounds per annum in the form of subscriptions, from those who would be willing to join the Society, if not asked to pay an entrance fee. Therefore, for the sake of receiving £222 cash, according to my way of thinking, we shut out a considerable annual income. The next point is—the hope expressed—"that many members will join the Society;" this brings us to a most important question. I do not believe there is a more important one in connection with our Society. During the past year we have had fifty pharmaceutical chemists who have passed their examination; and out of this fifty I understand from Mr. Bremridge that twenty-five have joined the Society. Of chemists and druggists there have been 234 who have passed the Minor examination, and 123 the Modified, making a total of 357, whilst only fifty of these have aspired to the higher title of Pharmaceutical Chemists; and out of those fifty, only twenty-five have joined the Society. Now we cannot forget that our Society to a large extent is governed by its members; the Council itself must consist of two-thirds of pharmaceutical chemists; and if, during the year, we only increase our number by twenty-five, and at the same time a large number, by old age and in other ways, is removed from us, it follows that in course of time we shall absolutely be in danger of not having sufficient men to undertake the responsible duties of the Society. The question I should like to lay before you is this—In what way can we render the higher character of membership of the Society something to be desired and aimed at by these men? We must bear in mind that at the present time a man may come up and pass the Minor examination, receive a certificate of qualification, and then go forth into the world with the stamp of competency. Previous to the Act of 1868, the Minor examination was but the stepping-stone to the higher one, which conferred the degree of pharmaceutical chemist; and it was the general expectation of those who were officially connected with the Society at that time, that those who passed the Minor examination, would go on to the Major, and thus qualify themselves to become members. But now things are altered. Those who now join the Society, not being in business before 1868, are not called upon necessarily to pass the Major examination, but by simply passing the Minor, they are registered as Chemists and Druggists, and there is not the slightest necessity, unless they choose, for them to aim higher and take the title of Pharmaceutical Chemists. But unless they do so, they cannot become members of the Society, pharmaceutical chemists alone being eligible, and that is the important point. In what way, then, can we render that higher title more valuable and appreciated? My suggestion would be this. The Minor examination is a *sine quâ non*, without which no one can go into business; but the Major is an honorary title; and those alone who have extra abilities or ambition will push forward to it. Still, with the Minor certificate, a man stands in the eyes of the Government and the public as properly qualified to carry on business. I do not want to cast reflection, but I must say that some of those who only pass the Minor examination are not so fully qualified to take the responsible position of managers or masters of a business as they should be; and I think if some alteration were made with regard to the fees and to the substance of these examinations, a material improvement might be brought about. At the present time, the fee for the Preliminary examination is two guineas; for the Minor, three guineas; and five guineas for the Major; added to which again, when a man becomes a member—for that is what we should aim at—he must either pay one guinea per annum or twenty guineas commutation fee. Now, might not some alteration be made by increasing the fees for the Minor, retaining the five guineas for the Major, and abolishing altogether the fee on becoming a member. Two ideas suggest themselves to my mind; either that the fee for the Minor should be eight guineas, making with the two guinea fee for the Preliminary, ten guineas; retaining the fee of five guineas for the Major, which should then entitle the person to be registered as a member of the Society; or that there should be a small additional commutation fee, say, five guineas. Education has always been our bond of membership from the earliest days. We have held out that one idea, let a man be qualified, and then let him come into the Society; and I say, if a man has sufficient *nous* in him to press forward for the higher title, let him have some reward for it, either in the form of the freedom of the Society, or that a small fee only should be paid for life membership. I think also that the Minor examination, seeing it holds so important a position, and infers full qualification for business, should include rather more practical chemistry, analysis, toxicology, and so forth, which are not included at present. I will not say any more at present on this point, and would only add, with regard to the Benevolent Fund that certainly the mode of investment is open to a great deal of criticism, and, I think, might be much improved.

Mr. Giles: There is no doubt we have just had our attention called to a very important matter with regard to the future of the Society. It is one which all those who have paid any attention, and have looked to the future welfare of the Society, have seen dawning for many years. It is unquestionably the fact that we have withdrawn, in the spirit of liberality we have practised, many of the inducements which formerly existed to lead men on to attain the qualification of a pharmaceutical chemist by means of the Major examination. That is a very serious matter. On the other hand, we have had little anxiety about quality of the institution, but every anxiety about numbers. In future, the difficulty will be reversed; we shall have less anxiety about numbers, but more about our quality. With regard to the Juries Bill, I cannot quite enter into the spirit of satisfaction with which this has been regarded, for we are by no means out of the wood; we have simply got into the condition in which our difficulties may begin. As I understand, this Bill has passed the second reading, which is a sort of guarantee that the Bill in some shape or form will be carried; but we have only just arrived at that condition when its clauses will be examined on every matter of detail as a perfectly open question. Now, Sir, the clause that applies to us in page 4, by which apothecaries, certificated or registered medical practitioners and chemists and druggists, if actually practising shall be exempted, is all very well supposing that it passed; and I should be very pleased that all the members of our trade should participate in the advantage which at the present time is secured to pharmaceutical chemists only. But supposing that clause should not pass,—supposing there should be an objection to eliminate from the jury lists so large a body (and I will venture to say without any affectation of modesty, such a qualified body), what is the consequence? I find that one of the Acts repealed in this Bill is the Juries Act, which gives pharmaceutical chemists their exemption. Now that is a very important thing, and I think that while it would be very satisfactory that those who are practically engaged in the same trade should have the same advantages, yet I cannot help seeing, with considerable anxiety, the possibility of my losing that advantage which I have without their gaining it. Therefore, the best attention of our Council is still required to watch the progress of that Bill. We want it on all matters affecting the good of the Society. These meetings are very important, and the expression of opinion at them tends to strengthen the Council's hands; but in all matters of administration we must rely on the action of the Council itself, which is a more concentrated body. Very frequently questions arise which take their origin outside the Council, and, as an instance, I may take the question of provincial education. It has advanced a certain stage by external action very properly and advantageously; but at the same time—and I am now going to act the part of the judicious friend, in other words, as a wet blanket, in giving a word of caution on this matter—let us be careful not to go too far. It seems to be assumed by many speakers that this Society is an educating body. It is not; it never set itself up as such. It was established as a central organization of chemists and druggists, to promote education certainly, but never, as I understand, to provide it. The providing of education became to some extent associated with it from the circumstances of the time. It is surprising how little men govern the world, and how much it is governed by circumstances and the course of events. In the same way we have been led on to provide pharmaceutical education when we found that a large amount of qualification is demanded by the examiners; that there is no means of providing it, and that now some means must be taken to provide it. At the same time that is not the main duty of the Society or part of its constitution, though I admit it is our duty, both in our corporate and individual capacity, to aid in every way we can to promote it. At the same time do not let gentlemen run away with the idea that this Society fails to fulfil the purposes for which it was called into being if it does not provide means of education all through the country, which it is highly necessary should be provided. Do not let it be supposed that I am endeavouring to check the action which is being promoted in this direction. I perfectly agree with what has been said as to our adopting the principle of the Government schools, and acting in conjunction with them. These schools, as I have said before, are, I believe, destined to perform a most important service throughout the nation in an educational point of view, in furnishing a means which never had been provided before; and let us all in our respective neighbourhoods do what we can to promote these schools. I am a subscriber to them, and, but for other engagements, I should have been on the Board of Management of the one in Bristol. In point of fact the Government of the day desire, I believe, to encourage art and science education. We cannot fail to see that there is a strong desire on the part of the Government to foster, encourage and extend these schools, and I say that they are not only destined to provide a general scientific education throughout the country for persons who want it as a basis for their engagements in manufactures and in art, but they are also intended to subserve the necessities of pharmaceutical education. I also believe that the medical profession will give up their schools to the extent of their ordinary science teaching, and rely upon these Government schools for education in chemistry, botany, and so forth. I consider it is our duty to ally ourselves with these schools as much as we can, and to look forward ultimately to them as being the means of providing that general provincial education which is necessary for carrying out the necessities of the Pharmacy Bill by the education of our members throughout the country. At the same time I am not a great advocate for watching and waiting. I would not wait in entire indolence. I do not believe in the masterly activity which allows questions to solve themselves. I believe there is a real power in patience; but, at the same time, we cannot allow things to go on without endeavouring to do what we can. Therefore, I consider in the meantime it is the duty of this Society, until some more efficient means are called into being, to do all it can to promote the cause of pharmaceutical education, whether it be in London or in the provinces. I approve of this Report very greatly, and I particularly admire the caution with which that statement in the middle clause of the eighth page is worded,—it says, "It is eminently a question of considerable difficulty, requiring much careful thought, for whilst the desirability of carrying out such a project is generally admitted, it is obvious that it should be done equitably, and to be done equitably, it must be done systematically." We could not possibly at this meeting pronounce any opinion on anything laid before us as being sufficiently tangible for action; it must go back to the Council, and I hope we shall see this particular point well represented in the incoming Council. My vote has been largely influenced with that object, in order that those who have this cause at heart may also have the responsibility of carrying out their ideas, for I do not believe in anybody standing outside and begging that something should be done unless he will take the responsibility of carrying his views into action; not that I wish to impute anything of that sort. That is all I wish to say upon this point. But I feel obliged to state that I shall not be able to vote for the reception and adoption of the Report. If it were simply a question of reception, I would say nothing, but I cannot adopt that which I believe to be injudicious, and which I also believe to be untrue. I refer to the last clause of the Report, upon which I make no further observation than this,—I thought what we wanted at this time especially was conciliation, and why on earth any recollection of things that are passed should be brought forward again I cannot understand! I am sorry that the Council in an injudicious mood has said that which I cannot believe is strictly accurate. In an official document of this kind I think it is of all things desirable that you should be very guarded, and that nothing should be said which is open at all to misconstruction. I cannot admit that Mr. Forster's Bill was withdrawn in consequence of the action of this Society; nor can I admit that the Council had any official knowledge of its being opposed by a very large majority of the trade. I just take the opportunity of saying that if that Bill were brought forward again I should oppose it very strongly for this reason above all others, that it proposed to vest in the hands of the Council that which I say was a legislative faculty that ought to rest solely in the hands of the Society. If the Council were permitted to do that kind of legislative act, I say it would be exceeding its functions. I will not say any more about it, but it is impossible that this motion can be carried unanimously, because however unpopular I may be, I shall follow the rule which I have made, and have often found the value of it, namely, to stand by my opinions and vote accordingly.

Mr. Heald (Sleaford): The question of provincial education has, up to this time not been approached by anybody belonging to a purely provincial town, such as I come from, containing about 4000 inhabitants. I think masters in the country have many of them been harshly treated, and the shortcomings of apprentices have in most cases been attributed to the neglect or incapacity of the master, when, in a great many instances, the master has been not only willing but anxious that the apprentice should receive a scientific education, and the fault has been on his side in not availing himself of the advantages given. As a proof of that I may refer to a letter which I have here from a master in a small town referring to an application about an apprentice. He says the hours of business are from seven to eight in the summer and from eight to eight in the winter, except on Saturday, when they are later; that he allows time in the week when he expects the apprentice to collect plants; that he expects him to pass the Preliminary examination, and connect himself with the Society. I believe that is not at all an isolated example of what country druggists wish to do for their apprentices. There are a great many of us in the country towns who would be very glad to do these things; and many have passed their examinations without attending any lectures or receiving any instruction whatever. I do adhere to the old adage that "God helps those who help themselves," and I certainly should oppose any assistance being given to large centres like Leeds, Bradford, Sheffield, Manchester, and so on, while small country towns like the one I come from are left out in the dark. I believe the Pharmaceutical Society receives more support in proportion to the number of druggists in small towns than in large towns such as those I have named. In the town where I live there are five chemists, three of whom are members of the Society, and out of eight apprentices and assistants, I think there are four or five associated with us, which is a much larger proportion than we have had mentioned in the statistics given with regard to Leeds and other places. One gentleman alluded to Preliminary examinations, but I believe most country druggists are now insisting on lads passing the examination before they sign their indentures. I have adopted that plan myself, and I believe it is becoming general. With regard to the entrance fees, I believe the abolition would be a good thing, for I know two druggists who would have joined immediately after the passing of the Pharmacy Act had it not been for the entrance fee of two guineas. As another reason why more chemists do not join, I am afraid from what I have seen in the the Journal that the Society does not really stick up for the interests of the country trade in the manner it ought to do.

Mr. Carteighe (London) suggested that as all seemed agreed upon the necessity for provincial education, it was not desirable to spend more time in discussing mere matters of details, which must be left to the Council to carry out.

Mr. Sutton (Norwich) said: I quite agree that we need not spend more time on this matter, but I should like to refer for one moment to the statistics of the examinations given in the Report. I find that in the Major examination, the percentage who pass is 71, the Minor 63, Modified 65, and Preliminary 66. I am quite prepared to believe that on the whole, that is a fair proportion; but I certainly think it is a great shame that we have a failure of one third in the Preliminary examinations, and I do hope it will go forth from this meeting as an expression of opinion that masters should be more careful in selecting their pupils or apprentices. I do not mean so much with regard to the premiums they receive, but in seeing that they have been carefully and properly instructed before they attempt to enter the business. If we do so, we shall place the Society in a higher position than it is now in, and I hope it will be borne in mind and acted upon year after year.

Mr. E. Burden (London): The question of education is no doubt, of great importance, but I think what I am about to speak of is of nearly equal importance, and I am sure I shall have the sympathy of all who hear me. It has been thrown out by two or three gentlemen who have spoken this morning, that something might be done to employ the money belonging to the Benevolent Fund to better advantage for the Society. I also remember that last year we had no candidates for pensions beyond those who were previously elected, and therefore the fund is to some extent lying idle, which seems an unfortunate occurrence. A short time ago it was suggested to me that possibly it might be a good thing if, in conjunction with the Benevolent Fund, we could establish a life insurance society, which should be taken up by all the members. We cannot forget that throughout the country we are not, as a rule, a rich body of men, but on the contrary many of us are not so wealthy as other trades, and I think if we could employ the Benevolent Fund in some way as an insurance for our widows and orphans, it would be a great advantage. I find that in 1861 the census showed that there were 16,000 chemists in the United Kingdom, including assistants; and according to the present Report, we numbered at the close of last year, nearly 2500 members. This number is quite large enough to form a life insurance society for the exclusive benefit of chemists and druggists; and if our present offices and staff could to some extent be utilized, it would effect such an immense saving in the working expenses, especially as we have local secretaries throughout the country and should not require advertising, that it would enable the managers of such a society, under the guidance of an actuary, to adopt a scale of payments considerably below those required by ordinary insurance offices; I should say, and I speak after some inquiry, to the extent of 15 or 20 per cent. There are other and important arrangements which could be introduced, and it is here that I wish the application of the Benevolent Fund. We are generally a respectable body, and feel adverse circumstances deeply; and many hesitate, I believe, to come and ask for assistance even when they require it; but such a scheme would enable them to come with a better face, as they would feel they were not entirely asking for charity. For instance, a member unable to keep up his payments, might be assisted from the Benevolent Fund, so as to keep the policy on foot, or if he were unable or unwilling to keep up the premiums, the full value of his former payments might be secured to him payable to his family on his death; money also might be advanced in case of need on deposit of the policy with a bond by himself or other sureties, and annuities, and endowments; provisions for children might also be included. I think that if these advantages were put forward, such a scheme would be sure of success, and that we should meet with a response from nearly all the chemists and druggists in the kingdom. I dare say there are many in the trade who have not insured their lives, and here they would have a body to deal with which would have every consideration for them, which would consider each case; and if adverse circumstances occurred, and the policy could not be kept up, it would be in the hands of the Society, which would give the member its full value. Receiving aid in such a way would not entail the feeling of pauperism on the part of the recipients; and I hope, therefore, the subject will receive mature consideration from all parties. It is a matter which has grown upon me, and I feel its importance so much myself, that I shall be willing to co-operate with any gentlemen in carrying it out.

Mr. Smith (Walworth) said several cases had come to his knowledge during the last year of peculiar hardship, on account of the provision of law which compelled the widow of a pharmaceutical chemist to sell the business directly after his death, and he should very much like to hear if something could not be done by the Council to alter that objectionable clause in the Act. If any member died, his business could not be continued by his widow or daughter, but must be sold. He knew a case within the last six months in which a widow had to sell her business at a loss of over £400.

The President said that a business could be carried on for the benefit of the widow by trustees appointed for the purpose.

The Solicitor read the clause in the Act bearing upon the point, namely: "Upon the decease of any pharmaceutical chemist or chemist or druggist actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such pharmaceutical chemist or chemist and druggist to continue such business."

Mr. Smith: For how long?

The Solicitor: There is no limit "if, and so long only, as such business shall be *bonâ fide*, conducted by a duly qualified assistant."

Mr. Bannard said the last speaker was not singular in his opinion, for he had known a similar case.

Mr. Urwick said he had the arrangement of an estate, and, on writing to the Secretary, he had been informed that the business could be conducted by a qualified assistant.

The Solicitor further explained that the business could only be carried on by trustees, or executors, or administrators, not by a legatee. If a man died without a will, some one must administer in the estate, and he could carry on the business for the benefit of the widow; but the moment the estate passed to a legatee, then the executorship or trusteeship came to an end.

Mr. Reynolds (Leeds) said: Mr. Mackay had reproduced a statement from the Journal which put three northern towns in rather an invidious position. If he had read that article with a little more care he would have seen that whilst the average percentage of membership throughout the country was twenty, if the statistics given for those three unhappy Yorkshire towns were thrown into percentages, they came out Sheffield, twenty-seven; Leeds, twenty-four; Hull, nineteen; or an average of twenty-three and a third, a little better than the general average of the country. He would also point out that membership in the Society must not be taken as the only test of earnestness in the cause of pharmaceutical education, for the local associations had many more members. In his own town there were over fifty members of the local association who paid their half guinea a year, simply because they were in earnest in promoting education.

Mr. Mackay said he had only quoted the figures to show how natural it was that the Council should desire to have more evidence of support given to the Society, before making grants to any particular town.

The resolution for the adoption of the report was then put, and carried with one dissentient.

Mr. Vizer then said: Mr. Chairman,—I will endeavour to be as brief as possible in my remarks in introducing the resolution of which I have given notice; and I hope those who follow me will be brief also. The resolution is:

"That considering the altered position which this Society now holds under the Pharmacy Act, 1868, towards the trade, it is the opinion of this meeting that no resolution involving legal consequences, as contemplated by the first clause of that Act, should be received at any general meeting of the members unless fourteen days shall have been previously given to members by the Secretary by advertisement or otherwise. This meeting, therefore, respectfully urges upon the Council the importance of framing a Bye-law to that effect."

This resolution, Sir, is I think one of great and general interest to every member of our trade, whether he be inside or outside the pale of this Society. In the first place I would call your attention to the Act of 1852, which you will find really only legalizes the registration of a certain voluntary body. It states in the preamble that "certain persons are desirous of advancing chemistry and pharmacy and promoting an uniform system of education," and so on. I will not trouble you by reading the whole of that Act, but if you go through it clause by clause you will find that almost every one refers to the *registration* of a voluntary body. Now, the Act of 1852 was supplemented by that of 1868, which incorporated and embraced the previous Act, putting our trade in a wholly different position to that which it held before. Up to 1868 it was a matter of choice whether a person in trade chose to become a member of our Society or not; he was a perfectly free agent, and nobody could prevent him opening shop or carrying on business. But the Act of 1868 entirely alters the position of the trade. The very first clause says,—"It shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons (and so on), unless such person shall be a pharmaceutical chemist or a chemist and druggist within the meaning of this Act, and be registered under this Act, and (this is *the* point to which I wish to direct your particular attention) shall conform to such regulations as to the keeping, dispensing, and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council." If I may be allowed, I will for the moment omit all reference to the word "poison." Under this Act every chemist is bound to obey the laws emanating from 17, Bloomsbury Square. The Act in every way applies as much to the most isolated village chemist as to the most renowned of London establishment. No one can say now that he will not obey the laws of this Society, because the Government says he must. I believe it was stated last year by Mr. Giles that this meeting was 'omnipotent;' at any rate I say so to-day. This meeting *is* omnipotent according to the Act of Parliament. I would draw your special attention to the wording here; it does not say such regulations as shall be prescribed by the 'Council,' but by the 'Pharmaceutical Society,' and the 'Society' consists of the general meetings of the members. It is, I believe, the only clause in the Act in which the word "Society" occurs; but acting on that clause we may come to this meeting, and any resolution may be brought forward and passed, and after the consent of the Privy Council has been obtained thereto there is no power to alter it. I would ask your attention for a moment to that fact; in my opinion such unlimited power is highly undesirable to be vested in any meeting, where such large interests are involved. It may be said that this resolution would cripple or hinder our discussions. Not the least in the world. Discussion is one thing; but to put that discussion into the form of a resolution, to be accepted or rejected by a meeting, is another thing. We may discuss any question, but when it comes to a vote of Yes or No, then things are changed, and it is against that alone that my resolution points. We must bear in mind that we meet here as a body of members of the Pharmaceutical Society; but this Society does not embrace the whole trade. There is a large body, numerically far stronger than ourselves, outside the pale of the Pharmaceutical Society, and those gentlemen naturally and justly, I think, regard the action of our Society with a somewhat jealous eye. When they know that they are completely in the hands of our Society, it is but natural that they should like to know previously what subjects may crop up at these meetings; and hence, I think, the desirability of adopting the resolution I have now read. It is simply a matter of honest dealing, so that we may all know what we are about, and that nothing may be brought forward under this clause without due notice. It may be urged again, that circumstances may arise where it would be very important that immediate action should be taken; but I apprehend that this resolution will in no way interfere with any such action. Such action would belong to the Council, and this resolution in no way fetters the hands of the Council, it simply regulates the action of our General Meetings with regard to the particular subject of this clause. Another objection which may be raised is, that we have the power of calling a special general meeting should any objectionable resolution be passed; but I apprehend that if a resolution had passed this meeting, it might obtain the sanction of the Privy Council and become law long before a special meeting could be called. I will now commend the resolution to the attention of the meeting, with the hope that it will be adopted. I would add that I have good grounds for supposing that many of our Council look upon it in a favourable light, and I believe its being adopted will strengthen the hands of the Council and benefit the trade at large.

Mr. Wade said: I second the resolution with great pleasure, because I think it will be for the benefit of the Society, and also the trade. I think the discussion that has taken place this day has all gone in favour of this resolution; and if it had not been that the sentiments uttered all appeared to me to tend to support this resolution, I should have taken an opportunity of making some remarks myself. It is evident that the Society desires to obtain the confidence of the trade at large. It has struck me for years past that there has been a confusion of ideas on this point whether intentional or not. There are two duties this Society has to perform, one in its capacity as being a corporate body, the other as a private society or club; but the two seem to me so wrapt up together, that that which is the duty to the trade at large becomes involved in that which is the privilege of the members of the Society. Nearly all the arguments have been so confused on this point that it appears to me to be almost impossible for the Council of the Society to perceive what is its duty to the trade at large, and what is its duty to the members as a private society; because, taking the Society, what is its position after all? Nothing more than a private privilege which people have on paying subscriptions. If such is the case, and if, as stated in the Journal, there are in Leeds, Hull, and other large towns, such an immense number of tradesmen who are not members of the Society, is it a matter of right or justice that you should on the spur of the moment bring forward any resolution and make it a law of the trade? Apart from that, I appeal to you on behalf of your own members. Your own members have allowed you to come here in confidence to-day, not having thought it necessary to come themselves, because they believe there is nothing likely to be done here that would be detrimental to their interests. There has been nothing sensational expected. They believed there would be simply a discussion on the Report, and a few other matters which would not be to their injury or affect their interests. But if it had occurred to any gentleman that this was a favourable opportunity, being a quiet meeting, when by getting a certain number of gentlemen who agreed with him he could pass a resolution, and if he had chosen to bring forward a resolution at this meeting, no one knows what injury might be done; and it would be impossible to prevent that becoming law. I ask you, therefore, to support this resolution, because I know that you have nothing in your minds but that which is fair and aboveboard, and this will ensure due notice being given beforehand of any important resolution such as I have referred to. You have said from the beginning that the Society has for its object, not simply present good, but also the future welfare of the whole trade; and in carrying out this idea, and recollecting that your private membership is entirely distinct from your action in a corporate capacity, and the powers entrusted to you by the Act of Parliament, I hope you will support this resolution which I have much pleasure in seconding.

The President said the resolution simply asked the Council to pass a bye-law requiring fourteen days notice of any resolution having legal consequences, and, therefore, he saw no difficulty in its being put.

Mr. Carteighe said he quite agreed that it was very desirable to have a fair field and no favour for anything which might be brought forward, but he thought many gentlemen present were not quite clear what it was that was proposed, and he would therefore suggest that the resolution should be withdrawn and the matter left in the hands of the Council. At any rate he should like to ask the solicitor what the legal consequence of the resolution would be.

The President said if Mr. Vizer thought fit to withdraw the resolution, he was authorized to say that Mr. Brown, who had been balloted upon the next Council, would undertake to bring forward the subject at the earliest possible opportunity.

Mr. Giles said if they passed the resolution it would go as a request to the Council to pass a bye law to that effect. He was not quite clear about the matter himself, because it seemed to him they were going to tie their hands, and it was a very good rule in business never to tie up your own hands. He did not see any likelihood of any harm arising if this were simply intended to prevent surprise and things being brought forward at the general meeting which ought not to be without notice, and without being properly debated by all interested.

Mr. Atkins thought the resolution asked the meeting to do what it condemned itself.

Mr. Vizer said that was not the case, because his resolution involved no legal consequences.

Mr. Giles asked if such a bye-law would be operative if passed.

The President said the resolution before the meeting bound them to nothing except that it urged upon the Council the importance of forming a bye-law, that bye-law must come before a special general meeting before it could be confirmed.

Mr. Brown: I cannot see any purpose that can be served by passing the resolution, except as an intimation to the incoming Council of the feeling of this meeting and the feeling—which I believe is expressed by this meeting—of a considerable number outside. If Mr. Vizer, with the assurance that he has already received that this subject shall be brought forward at the very first meeting of the Council, sees fit to withdraw the resolution, I believe his purpose will have been answered, and time may be saved. The resolution itself cannot have any legal effect, as it is not competent for this meeting to undertake the question of an alteration of a bye-law. Proper steps must of a necessity be taken by the Council at its very first meeting, to produce an alteration in the bye-law as wished by the mover and seconder and evidently by a large majority of this meeting. That alteration will have to be considered at two subsequent meetings of the Council, and a special meeting of the Council will then have to be summoned to approve of the amended bye-law, and lastly it will have to be submitted to the Privy Council. I believe the alteration suggested by Mr. Vizer is a very proper and just one, for I do not think matters affecting our legal position should be brought forward at annual meetings without previous notice, and after having passed in a very thin and inattentive meeting should then be submitted to the Privy Council, and have full force of law binding on the whole trade. That is a state of things not to be desired in any point of view; and I do not think there is a member of the Council who would object to any proper and legitimate alteration that could be effected in conjunction with our legal adviser, to prevent such a thing. With that object I pledge myself that this shall have attention at the very earliest meeting of the Council, and if that will satisfy Mr. Vizer, and he will withdraw his resolution, I am perfectly sure that the feeling which has been expressed will have its influence upon the Council.

Mr. Vizer: I feel, after the assurances given by yourself and by Mr. Brown, which are amply sufficient to answer my purpose, I cannot do better than leave it in your hands, and therefore I beg leave to withdraw the resolution.

Mr. Wheeler (London) then drew attention to a pamphlet issued by the Associated Traders' Company, carrying on business at Bishopsgate Street Without, and also at Wigmore Street, containing announcements that prescriptions left before eleven in the morning would be ready by four in the afternoon, but those left after eleven, would not be ready until after eleven the next morning. He wished to know if this could be done legally, and if prescriptions could be dispensed at an establishment in no way connected with the Pharmaceutical Society. He had raised the question as distinctly as possible, and would not occupy more time about it, but should be prepared, if necessary, to submit a resolution. He would rather hear a little discussion upon it at first, if gentlemen were so disposed.

The President said this appeared to be a question affecting the co-operative store movement, and he did not think it came within the business of the day.

A Member thought there would be no harm in the solicitor answering the question whether it could be legally done.

Mr. Wheeler said he would submit a resolution in order to raise the question fairly, viz.: "That this meeting is of opinion that the dispensing of prescriptions by any association of traders not on the Register of the Pharmaceutical Society is illegal, and requests the Council, through their proper officer, to take such immediate proceedings as shall decide the question, in a court of justice.

Mr. Giles said he should be very glad indeed to second the resolution, but he thought the first step should be to ascertain from their legal adviser whether it was illegal. This was a subject of immense interest to all persons engaged in the trade, and if they were at all jealous of their privileges in any direction, it should be against these abominable institutions which were growing up amongst them, and which he ventured to say, were likely to produce not only very great social, but political mischief.

Mr. Mackay said the words which had been read by Mr. Wheeler appeared to show that the prescriptions were sent out to be made up by a properly qualified person. Before the Solicitor answered the question, it would be important to know whether they were made up on the premises.

A Member said he apprehended the Act did not allow it to be done even in that way.

Another Member said it was a common thing in the Haymarket. He had seen one of his own customers coming out of the co-operative stores with a bottle of medicine in his hand.

The Solicitor: Gentlemen, I fancy that your proceedings at this meeting are to a certain extent public property, and it may not be expedient for you to have explicit answers given to all questions you choose to ask. I can point out to you the clause in the Act of Parliament which says that it shall be unlawful for any person to sell, or keep open shop for the retailing, dispensing or compounding poisons.

A Member: Is that all?

The Solicitor: I know of no Act of Parliament in restraint of trade which goes further.

Mr. Wheeler: Most prescriptions do contain poison.

The President: The Council have given great attention to this subject. If you really want your solicitor's opinion, you should ask him whether if a prescription proved to contain poison and to be dispensed by one of these associations can be legally attacked, and whether it would be wise to do so, supposing it to be dispensed by a competent person of your own body.

Mr. Urwick: I would remind you, gentlemen, that this question ought to receive very careful handling. If you should find you could not sustain your proceedings, you would simply be acting as an advertisement to the store, so that I think the matter requires a great deal of caution. No one feels more than I do the evil of these stores, and if this system could be stopped I should only be too glad to do so, but at the same time we should be careful not to advertise them.

Mr. Wheeler: In the meantime the evil exists, and unless something is done to put it down it will increase. The question is, can that something be done legally?

Mr. Malden remarked that he did not think it proper for the Pharmaceutical Journal to be the medium of an advertisement to the effect which appeared in its columns not long ago, that the Co-operative Society in Oxford Street required a manager to conduct the chemist department. He thought such advertisements should appear in other journals.

Mr. Pickering asked if the Act applied to persons keeping a shop and employing a qualified person to make up medicines.

The Solicitor: I should advise without hesitation, that I, as an unqualified person, could not keep open shop for the sale of poisons, and cover myself by employing a qualified assistant; and I should also advise that what would apply to a single individual would apply to many.

Mr. Giles said it appeared to him it was a question of principle, and they wanted some assurance from the Council that it would not be allowed to drop. He should like the question to be thoroughly investigated with legal assistance. He understood that no one could keep open shop to dispense poisons unless he were himself qualified. He did not know whether the clause relating to executors affected it.

The Solicitor: So long as an executor, administrator, or trustee, carries on business as such, he is within the distinct protection of the Act of Parliament. But when he becomes a beneficiary in his own right, his character is changed, and he comes under the penal clauses of the Act.

Mr. Giles: I understand that if a man offends against the law he is amenable to the law.

The President: I think you may safely leave this in the hands of the Council to take such proceedings as they may be advised.

The Scrutineers having been appointed,

Mr. Jameson moved, and Mr. Vizer seconded, a cordial vote of thanks to the President and to the Council, which was unanimously adopted, and the meeting was adjourned until Friday morning at eleven o'clock.

NORTH BRITISH BRANCH.

Dr. STATEMENT OF ACCOUNT FROM JANUARY 1ST TO DECEMBER 31ST, 1871. **Cr.**

	£.	s.	d.		£.	s.	d.
To balance due to Honorary Secretary (Mr. Mackay) for 1870	55	6	6	By Amount lodged in Clydesdale Bank	155	6	6

EDINBURGH, *Feb.* 1, 1872.

Having examined the foregoing Statement of Account for 1871 with requisite vouchers, we found the same correctly stated and entered.

We may remark that the balance entered as due to the Secretary of £55 6*s.* 6*d.* really belongs to the Expenditure of 1870, as shown in previous account for that year, while there still remains available at the credit of the North British Branch of the Society £21 1*s.* 9*d.*, thus making the real expenditure in connection with the Society's operations in Edinburgh for 1871 £79 6*s.* 3*d.*

Signed { JAMES GARDNER. WM. AINSLIE. H. C. BAILDON.

ADJOURNED MEETING.

Friday, May 17th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The Scrutineers brought up their report as follows:—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Thirty-First Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:—

Voting-papers received		1677
Disallowed:—		
Informal (rejected by the Scrutineers, having more than 14 names left)	6	
Received by the Secretary, per post after date (May 13th)	43	
,, without name and address on envelope	16	
,, left open (sent by book-post)	3	
not under cover	4	
		72
		1605

Hills	1483	Urwick	818
Schacht	1409	Owen	754
Stoddart	1397

EDWIN B. VIZER, *Chairman*.

FREDERICK ANDREWS. MAURICE HOWELL.
WM. BOSTOCK. JOSEPH KETTLE.
EDWARD BERDOE. DAVID MORGAN.
THOMAS BURDEN. ATKINSON PICKERING.
HORACE DAVENPORT. FREDERICK TIBBS.
HENRY A GAMBLE. BENJAMIN M. TIPPETT.
WILLIAM GULLIVER. CHARLES E. TURNER.
JOHN HORNCASTLE.

May 16th, 1872.

The Chairman then declared the Council and Auditors for the ensuing twelve months to consist of the following Members:—

COUNCIL.

ATHERTON, JOHN HENRY, Long Row, Nottingham.
BAYNES, JAMES, 24, Waterworks Street, Hull.
BETTY, SAMUEL CHAPMAN, 6, Park Street, Camden Town, N.W.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
GREENISH, THOMAS, 20, New Street, Dorset Square, N.W.
HAMPSON, ROBERT, 205, St. John Street Road, E.C.
HASELDEN, ADOLPHUS FREDERICK, 18, Conduit Street, W.
HILLS, THOMAS HYDE, 338, Oxford Street, W.
MACKAY, JOHN, 119, George Street, Edinburgh.
OWEN, JOHN, 234, Upper Street, Islington, N.
RADLEY, WILLIAM VALENTINE, 74, Market Place, Sheffield.
SANDFORD, GEORGE WEBB, 47, Piccadilly, W.
SAVAGE, WILLIAM DAWSON, 30, Upper Bedford Street, Brighton.
SCHACHT, GEORGE FREDERICK, 7, Regent's Place, Clifton.
SHAW, JOHN, 24, Great George Place, Liverpool.
STODDART, WILLIAM WALTER, 9, North Street, Bristol.
SUTTON, FRANCIS, Bank Plain, Norwich.
URWICK, WILLIAM WALKER, 60, St. George's Road, Pimlico, S.W.
WILLIAMS, JOHN, 10, New Cavendish Street, W.

AUDITORS.

ANDREWS, FREDERICK, 23, Leinster Terrace, Hyde Park, W.
BARRON, FREDERICK, 2, Bush Lane. E. C.
HODGKINSON, WILLIAM, 127, Aldersgate Street, E.C.
HORNER, EDWARD, 20, Bucklersbury, E.C.
SQUIRE, WILLIAM, 5, Coleman Street, E.C.

The Scrutineers also handed to the President their report of the return for the election of Local Secretaries.

Votes of thanks were given to the Scrutineers and the Chairman, and the Meeting separated.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE SO-CALLED COUNTRY SCHOOLS,

Sir,—I am led to believe, in consequence of having made observations these past few years upon the so-called country schools, that to maintain them satisfactorily will be found to be impossible.

All the country schools complain: the general complaints being, 1st, want of students; 2nd, want of teachers; 3rd, want of funds. These may be the causes of the tottering state of many of them; also, as they cannot be remedied, may prove to be the cause of their collapse.

1st. Want of students. It is a great pity that the chief complaint should be this; for without a fresh supply of students each year, any classes or schools can hardly be expected. I say a *fresh* supply, because the experience of teachers is, that very few old students take a second course of instruction in the same subject or subjects. Large towns, like Liverpool and Manchester, are said to have a few hundred assistants and apprentices each; and yet, how few of this great number are impressed with a proper interest in the subjects treated of! We should naturally expect these large towns to have large and flourishing schools; but if a required number of students for the classes in a very large town cannot be obtained, how is it possible for smaller towns to form classes?

But some very large towns have not more than 100 chemists, the number of whose assistants and apprentices perhaps does not amount to 40; for I need hardly say that a great number do not keep any assistants, while the majority of the better-to-do only keep one assistant, or one apprentice; and it is the few who have two assistants or more. Now, supposing a large town with forty assistants and apprentices, I believe it to be impossible to keep classes afloat with this small number. On the classes opening, 30 out of 40 may attend the first course of instruction; the next season, instead of a larger number of students coming up, only about 10 attend; the year afterwards fewer still; and frequently, of these numbers, only one-half remain to the end of the course. 30 to begin with become 15; 10 the next session, before the end of the course, dwindle down to 5. This is the experience of the associations now in existence; and with these facts before us, why should we shout and agitate about more similar schools with such miserably small numbers?

2nd. Want of teachers. Assuming that there is a large number of diligent and earnest students—a number sufficient to keep up the classes year by year—the next point to treat of is the want of teachers.

I believe any one would say that the proper teachers for a school would be the educated pharmacists—the men who know well the philosophy of their trade; these are the men who will best know what the young pharmacist requires, who would teach more of pharmaceutical science than an *étranger* would ever dream of doing. But these men have unfortunately something else to do than teach.

One fault in the country schools (?) is that they have had teachers who are a little better than nobody. What can we expect a clergyman to know of pharmaceutical botany or materia medica? Would it ever occur to him to treat of the different kinds of senna, or of the difference between aconite and horseradish, etc.? Would a schoolmaster who has dabbled in chemistry six months and taken "a certificate" ever think of, or ever be able to detect corrosive sublimate in calomel? And who could best treat of emulsions, plasters, pill-masses, mixtures, etc? I repeat that the educated pharmacists are the proper teachers; the services of others cannot be of much good.

3rd. Want of funds. Admitting further that both students and teachers are obtained, we now come to the very important question, how are the expenses of the school to be met? The small fees which the students of a country school pay will not cover even the teacher's expenses of one course of instruction, and then how about the other courses required? The question of cost—one supporting my idea of impossibility—is very little thought of. Country schools (if any), must be self-supporting. I do not see any alternative. I could easily show that it is very unfair of the Society to grant aid to the country schools. Moreover, no aid whatever should be expected, seeing that a very small proportionate number of chemists and apprentices in the country contribute anything to the "Alma Mater" which is so ignorantly spoken of. Contributing nothing to her, she cannot justly give anything to them in return.

A COUNTRY MAJOR ASSOCIATE.

G. C.—Your previous question was misunderstood, owing to your having misused a technical term. Your present question has reference to what is commonly called *molecular rotation.* In studying the various phenomena by which it is manifested, you will not find the microscope of service, but will require a piece of special apparatus, which you can construct yourself at small expense by utilizing the Nicol prisms of your microscope. Take an ordinary three-armed retort stand; to the lower ring or arm attach either your polarizing prism or, preferably, a bundle of glass plates inclined at the polarizing angle. In the upper ring fix your analysing prism. The fluid to be examined should be placed in a narrow tube about eight inches in height, attached to the middle arm. If your prisms be crossed before inserting your fluid, possessing rotatory power, you will find on introducing it that light is permitted to pass through the analyser, and is coloured. If you employ a solution of sugar, and you observe that the light which passes through the second prism is red, and that on rotating the analyser towards the right, the colour changes to yellow, and thence through green to violet, you may conclude that the rotation is right-handed. If, on the other hand, you have to turn the analyser towards the left hand, you must conclude that the polarization is left-handed. These phenomena, you will observe, are wholly distinct from those accompanying the action of doubly refracting substances upon plane polarized light. It is not easy to explain within these limits the course to be followed in ascertaining the amount of rotation produced by different substances. Monochromatic light must be used. Suppose you are examining a sugar solution with prism crossed, and the index attached to the analyser pointing to zero. When the sugar is introduced you will find it necessary to rotate the analyser, say 23° to the right, in order that the light may be extinguished. This is the amount of rotation for that particular fluid at its density and for that height of column. As the arc varies with increase or decrease of density and height of the fluid, it is needful to reduce it to a unit of height and density. The following formula is that given by Biot:—P = quantity of matter in a unit of solution; d = sp. gr.; l = length of column; a = arc of rotation; m = molecular rotation. Then $m = \frac{a}{l\ p\ d}$.

W. F. C.—(1) The first two cases in reference to which you inquire seem to be of such a nature as to require being "dealt with as they arise." Inasmuch as they assume sales that are somewhat unusual, as to quantity and frequency, it would doubtless be appropriate for the seller to caution his customer as to nature of the articles sold over and above mere literal compliance with the provision of the Act, unless it were within the knowledge of the seller that such precaution would be unnecessary. (2) The sale of poisons, according to the Pharmacy Act, is restricted to registered chemists and druggists.

Astonishment.—We cannot publish a letter founded on hearsay. We recommend you to communicate with the gentleman in question, and ask him whether the statement is true.

The following journals have been received:—The 'British Medical Journal,' May 11; the 'Medical Times and Gazette,' May 11; the 'Lancet,' May 11; the 'Medical Press and Circular, May 14; 'Nature,' May 11; the 'Chemical News,' May 11; 'English Mechanic,' May 10; 'Gardeners' Chronicle,' May 11; the 'Grocer,' May 11; the 'Journal of the Society of Arts,' May 11; 'Grocery News,' May 11.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Yewdall, Mr. Rimmington, Mr. Wilkinson, Mr. W. S. Bryant, Mr. Schacht, Mr. Brunt, Mr. Druce, Mr. Powell, G. T., G. C., "One who Failed on April 8th," "An Associate," "Amateur," "All Work," etc.

SALE OF JAVA BARK AT AMSTERDAM ON 14TH MARCH, 1872.

BY. DR. J. E. DE VRY.

Although small lots of Java bark had already been brought in public auction in 1870 and 1871, it was not before last March that any important quantity of that bark was offered for sale. The lot consisted of about 5800 kilogrammes, comprising the barks from five different species of Cinchona, viz.:—

1. *Cinchona Calisaya*, 1970 kilogr.
2. *C. Hasskarliana*, Miq. (*C. Calisaya hybrida*, De Vry), 690 kilogr.
3. *C. Pahudiana*, 2900 kilogr.
4. *C. officinalis*, 190 kilogr.
5. *C. succirubra*, 70 kilogr.

With the exception of No. 5 all the barks had a beautiful appearance and were admirably well packed, and I have no doubt that this good external condition contributed greatly to the high prices which these barks have realized; for these prices, as will be seen, are not in relation to the real amount of alkaloids contained in the barks.

The realized prices per kilogramme were the following:—

No. 1.—One lot (500 kilogr.) 3*s*. 8*d*. to 3*s*. 9*d*.
One lot (200 kilogr.) 4*s*. 10*d*. to 5*s*. 6*d*.
One lot (800 kilogr.) 5*s*. 2*d*.
One lot (250 kilogr.) 5*s*. 3*d*. to 5*s*. 4*d*.
One lot (220 kilogr.) 5*s*. 2*d*. to 5*s*. 4*d*.
No. 2.—One lot (250 kilogr.) 5*s*. 1*d*.
One lot (65 kilogr.) 5*s*. 2*d*.
One lot (75 kilogr.) 6*s*. 4*d*.
One lot (300 kilogr.) 6*s*. 4*d*. to 6*s*. 5*d*.
No. 3.—One lot (900 kilogr.) 3*s*. 5*d*. to 4*s*.
One lot (200 kilogr.) 5*s*. 2*d*. to 5*s*. 3*d*.
One lot (300 kilogr.) 5*s*. 3*d*. to 5*s*. 4*d*.
One lot (1500 kilogr.) 4*s*. 11*d*. to 5*s*. 4*d*.
No. 4.—One lot (60 kilogr.) 8*s*. 4*d*.
One lot (60 kilogr.) 8*s*. 8*d*.
One lot (70 kilogr.) 8*s*. 9*d*.
No 5.—One lot (70 kilogr.) 1*s*. 8*d*.

The chemical investigation of the mentioned barks gave the following results.

No. 1.—(Lot sold at 5*s*. 3*d*., to 5*s*. 4*d*.)
Total amount of alkaloids 1·5 per cent.
Molecular rotation of the mixed alkaloids [*a*] j = 85°·8 ↶.
Quinine: traces.
Ditto (lot sold at 5*s*. 2*d*.)
Total amount of alkaloids 2·1 per cent.
Molecular rotation of the mixed alkaloids [*a*] j = 58° ↶.
Quinine: appreciable traces.
No. 2.—(Lot sold at 6*s*. 4*d*. to 6*s*. 5*d*.)
Total amount of alkaloids 1·8 per cent.
Molecular rotation of the mixed alkaloids [*a*] j = 17°·5 ↶.
Quinine: 0·4 per cent.
No. 3.—(Lot sold at 4*s*. 11*d*. to 5*s*. 4*d*.)
Total amount of alkaloids 0·74 per cent.
Molecular rotation of the mixed alkaloids 90° ↶.
Quinine: traces
Cinchonidine dominates.
No. 4.—(The lot sold at 8*s*. 8*d*.)
Total amount of alkaloids 2·7 per cent.
Molecular rotation of the mixed alkaloids 109° ↶
Quinine: 1·07 per. cent.
No. 5.—
Total amount of alkaloids 1·86 per cent.
Molecular rotation of the mixed alkaloids 39° ↶.
Quinine: 0·3 per. cent.

I am sorry to state that these results seem to me very unsatisfactory, as they are much inferior to those obtained by me with the different barks from the plantations in British India.

The Hague, May 1, 1872.

Note on the above, communicated by
J. E. HOWARD, Esq.

Dr. de Vry having obligingly put at my disposal the specimens of the barks above described, with the option of either adding them to my collection or sending them to the Museum of the Pharmaceutical Society, I have preferred the latter course, and forward them accordingly. It will be seen that the results of the sale tend to confirm the views I have frequently expressed as to the Java barks. The (so-called) *Calisaya* has not the appearance any more than the qualities of the genuine bark,* and the *C. Pahudiana*, though a poor bark, equals it in value. I have sought to discriminate in a practical sense between the different and sometimes nearly allied forms of the Cinchonæ, and to this end have always regarded the differences of the barks as giving most material help in the classification; and, moreover, bringing pharmaceutical designations more into harmony with those of the botanists. In so doing I have experienced the usual lot of those who force unpalatable truths on unwilling ears, and have now the somewhat barren consolation of thinking that the advice given was the best I could offer, and that the present state of the produce of the Dutch plantations confirms my predictions. I am however pleased that my *C. Pahudiana* holds up its head as a distinct species, *distinct* in various particulars, and I think specially in the bark, from the *C. Carabayensis*, with which I pointed out its alliance in my first description. If the *C. Carabayensis* could produce any bark like the above it would doubtless, from its abundance, have become an article of import from South America.

* The *C. Calisaya*, var. *rugosa* (Miquel) is not, in my opinion, a *Calisaya* at all; the specimen of it which I have from Hasskarl, differs entirely from specimens of the true *C. Calisaya* in the same collection.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 863.)

"In Europe, Assmuss states that on being brought into the nest by the bee, the larvæ of the oil beetle leave the bee and devour the eggs in the bee-cells, and then attack the bee-bread. When full-fed and ready to pass through their transformations to attain the bee state, instead of at once assuming the pupa and imago state, they pass through a *hyper-metamorphosis*, as Fabre, a French naturalist, calls it. In other words, the changes in form which are preparatory to assuming the pupa and imago states are here more marked and almost coequal with the larva and pupa states, so that the *Meloe*, instead of passing through three states (the egg, larva and pupa), in reality passes through these and two others in addition, which are intermediate. The whole subject of the metamorphosis of this beetle needs revision, but Fabre states that the larva, soon after entering the nest of its host, changes its skin and assumes a second larva form (fig. 24), which somewhat resembles the larva of the Goldsmith beetle. Newport, who with Siebold, has carefully described the metamorphoses of *Meloe*, does not mention this stage in its development, which he calls 'pseudo-chrysalis.' It is motionless; the head is mask-like, without movable appendages, and the feet are represented by six tubercles. This is more properly speaking the semi-pupa, and the mature pupa grows beneath its mask-like form, which is finally moulted. This form, however, according to Fabre, changes its skin and turns into a third larva-form (fig. 25). After some time it assumes its true pupa form (fig. 26), and finally moults this skin to appear as a beetle (fig. 22)."

"There are other vesicatory beetles belonging to the genus *Meloe*, so named, it is supposed, because they are of a black or deep blue-black colour. They are called oil-beetles in England, on account of the yellowish liquid which oozes from their joints in large drops when they are handled. Their head is large, heart-shaped and bent down, as in the other blistering-beetles. Their thorax is narrowed behind, and very small in proportion to the rest of the body. The latter is egg-shaped, pointed behind, and so enormously large that it drags on the ground when the beetle attempts to walk. The wings are wanting, and of course these insects are unable to fly, although they have a pair of very short oval wing-covers, which overlap on their inner edges, and do not cover more than one-third of the abdomen. These beetles eat the leaves of various kinds of buttercups.

From the remarks of Dr. Hermann Burmeister it would appear that four species of *Meloe* are found, and more or less employed in the Argentine Provinces,* *i.e.* :—

Red-spotted Oil-beetle, *Meloe miniaceo-maculatus*, D'Orb.; dull black; elytra with rounded minium-red spots, two at the base, and a third nearly apical, about three-quarters of an inch long. Found on Malvaceous plants.

This species is figured in D'Orbigny's voyage to South America ('Insecta,' t. 15. f. 6). It is easily recognized by the red spots on its small elytra, and occurs in the interior of the province of Buenos Ayres.

Klug's Oil-beetle, *Meloe Klugii*, Erichs.; black; elytra with three yellow spots; abdomen of a sanguineous brick-red.

This species is described and figured—by Brandt and Erichson—in the Transactions of Acad. Cæs. Leop. Cur. vol. xvi. pl. i. p. 103. t. 8. It is found in Banda Oriental.

Two others were found and first described by Burmeister,—*Meloe sanguinolentus*, Burm., in Mendoza; *Meloe ebeninus*, Burm., in Catamacca.

All these species are enumerated in the 'Revista Farmacéutica,' of Buenos Ayres, for January, 1865.

This completes the list of Coleopterous insects, which have, or have had, any reputation in medicine. It only remains briefly to enumerate the vesicants found amongst other insects, and the adulterants which have been found mixed with the officinal Cantharides.

XI. Miscellaneous.

In addition to the vesicants furnished by the Order *coleoptera*, there are some few others which deserve notice, derived from other Orders of insects. Amongst these we include the one spider which has acquired a reputation for this property.

Blistering Spider, *Clubiona medicinalis*, Walck.; abdomen oval, increasing slightly towards the posterior extremity, which is very much rounded, of a bluish-black, with a pale longitudinal mark near the corselet, and five stripes of the same colour, the last forming a triangle, which is brighter; feet, with brown spots.—Walck. Aptères, vol. i. p. 607. *Tegenaria medicinalis*, Hentz, Journ. Acad. Sc. Phil. ii. p. i. page 53. pl. 5. fig. 1 *a*.

Moquin-Tandon says, "According to Hentz there is in the United States a species of spider (*Tegenaria medicinalis*, Walck.) which the inhabitants use as a blistering agent. This species is common in the neighbourhood of Philadelphia. Similar properties are attributed to *Clubio medicinalis*." These seem to be the same, as far as we can trace, and the *Tegenaria medicinalis* of Hentz would be synonymic with the *Clubiona medicinalis* of Walckenaer.

Chinese Red Lady-bug, *Huechys sanguinea*, Amy.

Dr. Porter Smith has drawn attention to this insect in his recently published Materia Medica of China, and afterwards in a note published in this Journal (p. 4), from the *Medical Times*. It is the chu-ki, or ailanthus bug, called the "Red Lady-bug" in the book above alluded to. It belongs to the *Homoptera*, and frequents the *Ailanthus*, and other trees. The head, thorax, and legs are black; the prothorax is red; the eyes are very prominent; a large, bright red spot on each side of the thorax above; the front pair of wings are dark brown, appearing nearly black when closed on the back of the insect; the hind pair of wings are pale, with brown veins; and the belly is of a bright vermilion-red.

Dr. Smith states that they are capable of raising a blister, but are much less powerful than the *Mylabris*, with which they are combined in the treatment of hydrophobia. The legs and wings are removed, and the bodies only are used for medicinal purposes.

For other particulars we may refer the reader back to page 4 of the present volume.

Andol-andol.—This vesicant has already been alluded to (p. 424). It is obtained from Java, but we have no clue to the order of insects to which it belongs.

Indian Bhir-buti.—In the Punjab is found an insect called "Bhir-buti," which is of a "beautiful scarlet colour, resembling a piece of scarlet velvet. These are collected during the rains, and yield an oil. They have a use similar to cantharides, as a blister and irritant." This is all the information we possess, for which we are indebted to Baden Powell's report on Punjab Products.

Processionary Caterpillars, *Cnethocampa processionea*, and *Cnethocampa pityocarpa*.

The caterpillars of two species of moth are believed to possess powerful irritant properties. The fine hairs with which they are clothed cause great irritation when they come in contact with the human skin, but they probably act merely in a mechanical manner. The ancients employed urticating caterpillars in the formation of sinapisms. Réaumur and Dorthes thought that when pounded, they might, under certain circumstances, be made useful as a

* Pharm. Journ., Ser. 2. Vol. VI. p. 548.

substitute for cantharides. An instance of the effect of these hairs is quoted from a French journal in Christison on Poisons (p. 617), "A child, ten years old, had a common blister applied to the neck and spine as a remedy for deafness, and four days afterwards her mother dressed the abrased skin with the leaves of beet-root, from which she had previously shaken a great number of caterpillars. The child soon complained of insupportable itching and burning in the part, and endeavoured to tear off the dressings. The mother persevered, however, and the child died in two days of gangrene of the whole integuments of the back. The surgeon who saw the child on the last day of her life ascribed the gangrene to the insects mentioned above, and states that they possess the power of exciting erysipelas when applied even to the sound skin." Although not found in Britain, these caterpillars are common on the Continent, where they often become a very great nuisance, on account of their urticating hairs. They abounded in the woods which, before the late war, skirted the city of Paris. In the Bois de Boulogne they considerably damped the ardour of citizens when they were abundant. When the webs were more than usually plentiful, as in 1865, parts of the wood were closed by the authorities against promenaders. In the southern departments of France the danger of coming in contact with "chenille vénéneuse" is so much considered that persons compelled by business to be near a tree infested by them are recommended to envelope their bodies in oiled linen. For further particulars on this subject we may refer to an article on "Processionary Moths," by the Rev. W. W. Spicer, in 'Science Gossip,' No. 77. (1871.)

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Spiritus Rectificatus.

[§ Alcohol C_2H_6O, with sixteen per cent. of water.] Specif. grav. ·838.

A moderately dilute solution of sugar to which some yeast has been added, kept at a temperature of 70° to 80° F. very speedily effervesces from the escape of carbonic anhydride; and if after the fermentation is over, the liquid is submitted to repeated distillation, the more volatile portion being each time collected, alcohol in an impure state is ultimately obtained. If cane sugar is employed, it is first converted into glucose,

$$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6.$$

And this subsequently splits up.

$$C_6H_{12}O_6 = 2CO_2 + 2C_2H_6O.$$

But the reaction is in reality much more complex than such an equation would indicate, glycerine and succinic acid having been detected in the residue of the distillation, and the development of the yeast demands the production of cellulose and fatty matter. Moreover, as ordinarily conducted, the fermentation of saccharine solutions yields small quantities of other alcohols, of which some are homologous with ordinary alcohol, as for instance

Propylic alcohol	C_3H_8O.
Butylic "	$C_4H_{10}O$.
Amylic "	$C_5H_{12}O$.

Others, though possessing the same composition as these bodies, possess different properties; are in fact *isomeric* with them. These liquids are less volatile than ordinary alcohol, and are almost entirely separated by the process of rectification. They constitute the liquid known as 'fousel oil.' The test of the B. P. is intended to indicate that traces only remain.

[§ Four fluid ounces with thirty grain-measures of the volumetric solution of nitrate of silver exposed for twenty-four hours to bright light, and then decanted from the black powder (metallic silver) which has formed, undergoes no further change when again exposed to light with more of the test.]

When alcohol and water are mixed, the liquid becomes warm, an effervescence occurs from the expulsion of the air which the water held in solution; and after the mixture has cooled, it will be found not to measure the sum of the volumes of the two liquids; contraction has taken place. Consequently, the strength of a given sample of dilute alcohol cannot be inferred from its specific gravity, which is greater than the calculated mean. The rectified spirit of the Pharmacopœia is a mixture of alcohol and water containing 84 parts per cent. by weight of the former. It is also often spoken of as being 56° over proof,—this means that in order to reduce it to the strength of proof spirit 100 volumes must be mixed with water till, after contraction, they measure 156 volumes. Nearly 60 volumes of water are necessary for this purpose.

To detect alcohol in aqueous fluids, it is sometimes sufficient simply to saturate with dry carbonate of potassium, when the alcohol separates and floats upon the surface, and may be recognized by its inflammability and other properties. But when the quantity is too minute to be detected in this way, Lieben's test may be used. Add to the liquid a grain or so of iodine and a few drops of caustic soda; warm gently, and then allow it to stand for a time. Iodoform is deposited as a yellowish crystalline substance.

$$C_2H_6O + 4I_2 + 6NaHO = CHI_3 + NaCHO_2 + 5NaI + 5H_2O$$

The iodoform may be recognized when mere traces are produced by examining the deposit under the microscope. The crystals present the appearance of hexagonal plates, or sometimes six-rayed stars. It is said that 1 of alcohol in 2000 of water may be detected by this test.

To obtain *absolute alcohol*, that is alcohol free from water, the Pharmacopœia directs to remove the first greater portion of the water from rectified spirit by means of carbonate of potassium, and afterwards to dehydrate by burnt lime. To deprive it of the last traces of water, the spirit, after the foregoing treatment, should be boiled with quicklime for about an hour in a flask with inverted condenser, and then distilled. The specific gravity of absolute alcohol at 60° F. is ·7939, and boiling-point, under the standard pressure of 760 m.m., is 173·6° F. (78·4° C.).

Alcohol, when acted upon by acids, furnishes by double decomposition a series of ethers which may be regarded as salts of a compound hydrocarbon radicle of which alcohol is itself the hydrate, *e.g.*—

$$C_2H_6O + HCl = C_2H_5Cl + H_2O$$
$$C_2H_6O + HC_2H_3O_2 = C_2H_5\,C_2H_3O_2 + H_2O$$
$$C_2H_6O + H_2SO_4 = C_2H_5\,HSO_4 + H_2O$$
etc. etc.

Ordinary ethylic alcohol is usually taken to be the type of the class of bodies known as "alcohols." They are characterized by giving, by double decomposition with acids, compounds similar to those above enumerated. The members of the group of primary alcohols to which common alcohol belongs furnish, when oxidized, aldehyds and acids, containing in each molecule the same number of atoms of carbon as themselves. Thus ordinary alcohol gives acetic aldehyd and acid.

$$2C_2H_5HO + O_2 = \underset{\text{Aldehyd.}}{2C_2H_3OH} + 2H_2O$$
$$C_2H_5HO + O_2 = \underset{\text{Acetic acid.}}{C_2H_3OHO} + H_2O$$

Spiritus Tenuior.

Take of

Rectified Spirit, 5 volumes.
Distilled Water, 3 volumes.

Mix.

The product has the specific gravity .920, and contains $49\frac{1}{4}$ parts of alcohol in 100 by weight.

REMARKS ON PLANTS FURNISHING VARIETIES OF IPECACUAN, AND ON THE CULTIVATION OF CEPHAELIS IPECACUANHA (RICH.) IN THE ROYAL BOTANIC GARDEN OF EDINBURGH.

BY PROFESSOR BALFOUR.*

Plants yielding various kinds of Ipecacuan belong to the Natural Orders Cinchonaceæ (Rubiaceæ, section Cinchoneæ), Violaceæ, Polygalaceæ, Asclepiadaceæ, and Euphorbiaceæ.

In the Order Cinchonaceæ, there are the following species:—

1. *Cephaelis Ipecacuanha* (Rich.) which yields the annulated or Lisbon Ipecacuan of commerce.
2. *Psychotria emetica* (Mut.) yielding striated Ipecacuan.
3. *Richardsonia scabra*, St. Hilaire, furnishing white or undulated Ipecacuan.
4. *Borreria ferruginea*, DC.
5. *Borreria Poaya*, DC.
6. *Manettia cordifolia*, Mart.

In the Natural Order Violaceæ, the following species are mentioned as furnishing emetic roots:—

1. *Ionidium Ipecacuanha*, Aug. St. Hil.
2. *I. microphyllum*, H.B.K.
3. *I. Poaya*, Aug. St. Hil.
4. *I. parviflorum*. Vent.
5. *I. brevicaule*, Mart.
6. *I. urticæfolium*, Mart.

In the Natural Order Polygalaceæ we find the following species:—*Polygala Poaya*, Spix. and Mart.

In the Natural Order Asclepiadaceæ we have the following species:—*Tylophora asthmatica*, W. and A.

In the Natural Order Euphorbiaceæ the following species is used:—*Euphorbia Ipecacuanha*, L.

The roots of these plants have been used as emetics in various parts of the world, and they agree to a certain extent in being more or less annulated or striated.

Cephaelis Ipecacuanha of Richard, the true Ipecacuan plant, has been cultivated in the Edinburgh Botanic Garden for at least forty years; but it was not propagated to any extent until the recent demand for it in India. This demand arose from the destruction of the plants by the collectors in Brazil, and the fear expressed that ere long this valuable remedy for dysentery might become scarce and dear. The Secretary of State for India resolved to attempt the propagation of the plant in India. Being asked for a supply of plants from the Edinburgh Botanic Garden, I set about the propagation of it. Mr. M'Nab found that this could be readily done by making cuttings of the annulated root.

Auguste de Saint-Hilaire, in his 'Plantes usuelles des Brasiliens,' alludes to the easy propagation of the plant both by seeds and cuttings, and also refers to the risk of its eradication:—

"Quoique cette dernière espèce ait été détruite dans les environs de Rio de Janeiro, et en général dans ceux des grandes villes, elle est encore fort commune dans beaucoup d'endroits; cependant comme on l'arrache sans prévoyance, qu'on n'attend point pour cela la maturité de ses fruits, et que, d'un autre côté, on détruit tous les jours de vastes portions de bois vierges où elle naissait en abondance, il est incontestable qu'elle ne tardera pas à devenir rare, et il serait important que l'on songeât sérieusement à la cultiver. Des essais tentés par plusiers personnes prouvent qu'elle se reproduit également bien par des semis, et par des boutures. Elle n'exige presque aucun soin, quand on la cultive dans les bois à l'ombre des grands arbres; mais, quand on est obligé de la cultiver dans des lieux découverts, il est nécessaire de lui procurer un ombrage artificiel."

An account of the method pursued in propagating the plant has already appeared in the Proceedings of the Society (vol. x. p. 318). Besides greatly multiplying the plants by this method from the specimens which had been long in cultivation, means were taken for importing living specimens from South America. Dr. Christison has taken a warm interest in the matter; and on our writing to Dr. Gunning, of Palmeiras, Rio Janeiro, a graduate of this University, he readily gave his aid, and sent to Edinburgh, on two occasions, boxes containing specimens, from which we were enabled to procure a large number of living plants by the mode of propagation adopted by Mr. M'Nab.

On examining these new plants, there appeared to be a marked difference between them and the old plants cultivated in the garden. The latter are evidently the form figured by Sir William Hooker, in the 'Botanical Magazine' (Tab. 4063), while the former resemble more the figure given by Martius in his 'Specimen Materiæ Medicæ Brasiliensis' (Tab. 1).

The old garden plant figured by Hooker was sent to him by Mr. Mackoy, of Liége; and this form seems to be still cultivated in Belgium, as the Messrs. Lawson have lately received specimens for their nursery from that country. It is distinguished from that sent by Dr. Gunning, by having leaves of a firmer texture, more elliptical or oval, the apex less pointed, and the edges wavy, with fewer hairs on their surface and at the edges. The stem is more shrubby. The plant flowers readily after a year's cultivation from slips. The style is short.

In the plant recently imported from Rio Janeiro, the leaves are more acute, more delicate in texture, and more hairy on the edges, and not wavy. The stem is not shrubby. It corresponds, apparently, with the figures and descriptions of Richard, Martius, and Auguste St. Hilaire. We require the flower, however, to determine more fully the character of the plant. Judging from the figures given by the above-mentioned botanists, the style in the Ipecacuan plant is so long that the two-lobed stigma reaches to the level of the anthers. We cannot say if this will constitute a character of importance. There may be hermaphrodite and dimorphic forms of the plant. Some may have short styles, and some long styles; and the reason why the flowering plants in the garden have never produced seed may be that long styles are required for complete fertilization.* To this point attention will be directed should the Rio Janeiro plant produce flowers in the garden. The roots

* Read before the Botanical Society of Edinburgh, May 11th, 1871.

* This year (Nov., 1871) several of the old Ipecacuan plants are showing fruit for the first time.

of both plants correspond with the Ipecacuan root of English commerce.

The native tribes of Brazil have long known the efficacy of the Ipecacuan root in the treatment of disease. The native names for it are Poaya de Mato and Cipo. In the Minas-Geraes it is called Ipecacuanha. The Ipecacuan plant appears to have been first noticed by Samuel Purchas in 'His Pilgrimes.' In this work he gives an account of voyages made to South America. He states that his treatise on Brazil (part iv. book vii. p. 1311) was written "by a Portugal friar (a Jesuit), who had lived for thirty years in those parts, from whom (much against his will) the written book was taken by Mr. Francis Cooke, of Dartmouth, on a voyage outward bound for Brazil, anno 1601, who sold the same to Master Hacket for twenty shillings, by whose permission it was translated out of Portugal into English." Mr. C. R. Markham mentions that this treatise was signed Mansel Tristan, Enfermero de Collegio de Baya. In it there is an account of a plant called Igpecaya, or Pigaya, which is said to be profitable for the bloody flux, and is supposed to be Ipecacuan.

In 1648 it was described and figured by Piso and Marcgrav in their treatises on the natural history of Brazil, which were published together, viz., Piso, 'De Medicina Brasiliensi,' p. 101, Marcgrav, 'Historia Rerum Naturalium Brasilæ," p. 17. It was then introduced into Europe. Grenier, a merchant, brought it to Paris as a pharmaceutical remedy, and as such it was used by Jean Adrien Helvetius, a medical man. It was brought under the notice of Louis XIV. Experiments were made at the Hôtel Dieu as to its efficacy in diarrhœa and dysentery. The origin of the name is doubtful. Some say *Ipe* (bark), *caa* (plant), *cua*, (scented), *nha* (striped), that is, bark of a scented and striped plant. Martius, in his 'Specimen Materiæ Medicæ Brasiliensis,' states that the name is corrupted into Picahonha, and by the Brazilians into Poaya. The latter name is applied generally in Brazil to all kinds of Ipecacuan plants. Weddell says that it is a corruption of the Indian words, Ycipo ayaca, which mean a twining (cipo), assuming a basket form (liane à panier, a basket twiner).

From Weddell's account in the 'Annales des Sciences Naturelles, Botanique,' tom. xi. (1849), 3 series, p. 193 *et seq.*, we gather the following particulars:—

Ipecacuan is found in parts of Brazil, bordering on the Atlantic, Para, Maranhao, Pernambuco, Bahia, Spirito-Santo, Minas-Geraes, Rio Janeiro, and San-Paulo. The plant also extends to Bolivia; it was seen by Weddell in Matto Grosso, a large Brazilian province far inland. He found it in shady parts of the province among such plants as *Euterpe oleracea*, *Œnocarpus Bacaba*, *Cocos capitata*, species of *Mauritia*, Tree-ferns, and *Iriartea exorrhiza*.

(*To be continued.*)

THE IDENTITY OF LIGHT AND RADIANT HEAT.

BY PROFESSOR TYNDALL, LL.D., F.R.S.

Whether we regard its achievements in the past, or its promise and tendency in the future, all that we know of physical science—every bent and bias which we receive from its pursuit—tends to confirm the dictum of the poet regarding this universe:—

> "All are but parts of one stupendous whole,
> Whose body Nature is." *

If I halt here, and omit the next clause of the couplet, it is not because physical science has arrived at any conclusion hostile to that clause, at all events in its profoundest signification, but simply because what the poet goes on to affirm lies outside the sphere of science. We, as physical students, have to do with "Nature" only, and our view of nature could not be more happily expressed than by the figure employed by the poet. For our vocation, and the delight and discipline that it confers, do not consist in the registration of unrelated facts and phenomena; but in the searching out and discovery of relationship in a system, whose parts we hold to be as closely and definitely related to each other as are the various organs and functions of the living body itself.

It was this spirit of search, this capacity and desire, developed amid natural agencies, to detect the lines of connection between these agencies, that gave for a time such keen interest to the discussion, whether light and heat were essentially different things, or whether a substantial identity subsisted between them. It is not so very many years since that most excellent experimenter and philosophical inquirer, Melloni, isolated from a solar beam a brilliant light, and finding it incompetent to affect his most sensitive thermoscopic apparatus, concluded that light and heat were essentially distinct. But in drawing this conclusion, Melloni forgot that he was implicitly dealing with an instrument of almost infinitely greater delicacy than his thermoscopic apparatus; he forgot that the human eye, and the consciousness connected with the eye, are capable of being vividly excited by an amount of force which when translated into heat might defy all the thermometers in the world to detect it. Melloni himself subsequently modified his conclusion.

It is not so very long since the late Principal Forbes was eagerly engaged in establishing the important point that radiant heat, like light, is capable of being polarized. Since that time Knoblauch, Foucault, Fizeau, and Seebeck have applied their refined experimental skill to this question of identity; and those excellent investigators De la Provostaye and Desains, pushed the analogy between light and heat so far as to prove that the magnetization of a ray of light, in Faraday's sense of the term, has its parallel in the magnetization of a ray of heat.

It was, however, in their private cabinets that these experimenters obtained their results, which were in most cases so small, as to require attention on the part of a skilled observer to detect them. But science grows, and our experimental means augment as our knowledge expands. Recent discoveries and improvements will, I trust, enable me to make evident to you, to-night, effects which have been hitherto confined to far more limited circles; some of which indeed have only been seen by the observers who first noticed and described them. And if those accidents which often hold sway over lecture-experiments of a delicate character should prove favourable, we may be able to push the subject a hair's breadth beyond the limits which observation has hitherto assigned to it.

Heat is presented to us in two aspects: sometimes associated with ordinary matter, through which it creeps by the process of conduction; sometimes not associated with ordinary matter, but, like light, flying through space with immense velocity. In this latter form it is called *radiant heat*. Radiant heat obviously and palpably comes to us from the Sun, but here it is entangled with light. Let me, in the first place, endeavour to unravel this entanglement.

When white light is refracted, it is unravelled and the spectrum is produced. A spectrum of the electric light was thrown upon a screen; and red, green, and black ribbons about an inch wide were successively moved along it. The red placed in the red light appeared a brilliant red; when moved into the green it became black. In like manner, the green ribbon moved from the green, where it shone vividly green, into the red, became an intense black. The black ribbon was black in every part of the spectrum.

Now the red ribbon is not heated in red, and the

* "All are but parts of one stupendous whole,
Whose body Nature is, and God the soul."
Pope's 'Essay on Man,' Epistle I. line 267.

green is not heated in green; but red is heated in green, and green in red. We have heating only where we have absorption; and the heat generated is the equivalent of the light absorbed. Black absorbs all the rays of light, hence, indeed, its blackness; and if it could speak, it might tell us the warmth of every colour. But warmth exists outside the colours. Beyond the red, where nothing is seen, the force acting on the retina is far greater than when the eye is plunged in the red. The objective here is entirely out of proportion to the subjective.

The existence of this heat was thus proved. All the colours but the red were cut off by a red glass, and with a diaphragm having a circular opening, a well-defined red circle was produced. This was refracted by a prism, still remaining a circle. A thermo-pile with its face towards the lamp was then caused to approach the path of the beam. It would have been seen by its shadow on the screen if the light had been at all invaded; but with a considerable interval between the pile and the light, a large defection of the galvanometer testified to the presence of heat beyond the luminous circle. An opaque solution* was substituted for the red glass. A circle remained, but it was an invisible circle of radiant heat instead of a circle of light, and the needle of the galvanometer did not fall, though the visible image had vanished.

Thus, as regards refraction, we have radiant heat behaving like light. And now for reflection. A horizontal beam of light was reflected upwards by a plane mirror, and when the light was cut off by the introduction of the opaque cell, a powerful beam of reflected heat was proved still to remain. The luminous beam was then *totally reflected* by a prism to a horizontal direction; the light was again cut off, and a powerful deflection of the galvanometer needle was obtained by the residual heat-beam. Thus, in respect to common and total reflection the behaviour of light and heat is the same.

The action of lenses on light and heat was then demonstrated, the invisible heat-rays being brought to a focus as readily as the rays of light.

A beam of light was then made to strike a concave mirror, and at the focus, which was strikingly visible in the dust of the room, the thermo-pile was placed, having its face covered. The light being cut off by the dark cell, and the covering screen drawn away, the needle of the galvanometer at once flew to its stops.

Double refraction by Iceland spar was next described and explained. It was illustrated by passing through the spar a circular beam of light, which, on the screen, gave two images. The places on the screen where these two images fell were marked, and the light was cut off by the iodine cell. On introducing the thermo-pile with its face towards the lamp, when it occupied the position of either light-image, a deflection of the needle was obtained. Of the two images, one is the ordinary, the other the extraordinary. Is the same true of the heat? Placing the pile in the place of the ordinary image, cutting off the light, and turning the spar, the deflection of the needle remained unchanged; but when the spar was turned round, while the pile occupied the place of the extraordinary image, the needle instantly fell. Why? Removing the dark cell and rotating the spar, the extraordinary light-image was seen to rotate round the ordinary one, which remained fixed. The heat-beam did the same and thus quitted the pile. Here then we prove that the heat-beam also has its ordinary and extraordinary image. This, it was believed, was the first time the effect had been obtained with purely invisible heat. Knoblauch had demonstrated the double refraction of heat, using the total beam, luminous and non-luminous of the Sun.

Some of the phenomena of polarization were next touched on. Light is propagated by the undulations of an etherial medium, the direction of vibration being perpendicular to the direction of propagation. A crystal of tourmaline has the property of quenching all vibrations except those which are parallel to the axis of the crystal; hence, a plate of tourmaline cut parallel to the axis will allow all vibrations in that direction to pass through it, but will stop all others. A beam of light which has passed through one plate of tourmaline is therefore unable to pass through another placed transversely to it, whereas, if the axes are parallel the light is but little dimmed by the second plate. The black space due to the superposition of the crossed plates of tourmaline was shown, as also the abolition of the darkness by a thin film of mica introduced between the plates.

A beam with all its vibrations reduced to the same plane is called a beam of *plane polarized light.*

The two beams emergent from double-refracting spar are thus polarized. Nicol got rid of one. He cut a parallelopiped of spar into two by a very oblique section, polished the two surfaces, and united them by Canada balsam. The ordinary or more powerfully refracted ray, at the surface of the balsam is, in consequence of its obliquity, totally reflected, and the extraordinary ray passes on alone. In this way we obtain an intense beam of polarized light.

A beam of light was sent through two large Nicol prisms, and shown to be entirely extinguished when the principal sections of the prisms crossed each other. The introduction of a plate of mica between them caused, as in the case of the crossed tourmalines, the instant reappearance of the light. The opaque cell was then placed in front of the lamp, all visible rays being thus intercepted. The thermo-pile was next placed so as to receive the beam after leaving the second Nicol prism. Causing one of the crossed prisms to rotate, a path was opened for the heat exactly as for the light, the deflection of the needle speedily bearing witness to the fact. The prisms being again crossed, the heat-beam was again quenched; but, as in the case of light, the introduction of a piece of mica restored the heat and caused a large deflection of the galvanometer.

Faraday's great experiment was next performed. A beam of light, polarized by one Nicol's prism, was made to pass through a piece of heavy glass placed between the perforated poles of an electro-magnet, and afterwards through another Nicol, so placed that the beam was extinguished. When the magnet was excited, the plane of polarization was caused to rotate and a luminous image flashed instantly out upon the scene.

The effect of magnetization is greatly augmented by adopting the device of MM. De la Provostaye and Desains, of causing the principal sections of the Nicol's prism to enclose, not a right angle, but an angle of 45°. This was done, the heat falling on the pile being neutralized by the method of compensation. On sending a current round the magnet a considerable deflection of the needle was obtained, the direction of the deflection depending on that of the magnetizing current.

De la Provostaye and Desains thus obtained with luminous solar heat a deflection of two or three degrees. With the iodine filter and the electric lamp a deflection equivalent to 150 of the lower degrees of the galvanometer was obtained from purely non-luminous heat.

ADULTERATION OF CHEMICALS IN THE UNITED STATES.

The following particulars as to adulterations of chemicals met with in commerce in the United States, are taken from the "Report on Adulterations and Sophistications" presented at the last meeting of the American Pharmaceutical Association.*

Acetic Acid.—Frequently weakened with water and

* Iodine in bisulphide of carbon.

* See also *ante*, p. 353.

adulterated with sulphuric acid. Six samples tested with chloride of barium gave a precipitate of sulphate of barium in varying proportions.

Muriatic Acid and *Sulphuric Acid*, sold as chemically pure, have both been found contaminated; the former with arsenious and sulphurous acids, the latter with a large proportion of sulphate of lead.

Tartaric Acid has been met with containing 50 per cent. of sulphate of magnesia. Alum is also said to be used as an adulterant, but the reporter had not seen a specimen.

Alum frequently contains iron, probably arising from carelessness in the manufacture. The presence of free acid has also been noticed, especially in the English article.

Carbonate of Ammonia is sometimes substituted by a compound made from solution of ammonia, glue and bicarbonate of soda, which forms when dry a hard translucent mass, resembling genuine carbonate.

Muriate of Ammonia is sometimes met with of very poor quality; iron is often visible on the surface and becomes still more so when dissolved. The report recommends that the purified granular salt should be the only one sold at the dispensing counter.

Black Sulphuret of Antimony has been met with containing sulphide of lead (galena), quartz (30 to 40 per cent.), clay, etc. A good article, however, is procurable.

Powdered Arsenic is sometimes adulterated with sulphate of lime or sulphate of baryta; the pharmacist is, therefore, recommended to purchase the lump arsenious acid.

Bismuth (metal) generally contains arsenic. An instance is mentioned in the report where 400 lb. of antimony was sold by a broker to a manufacturer for bismuth. Fortunately for the latter, he detected the error before the transaction was completed.

Subnitrate of Bismuth has been reported as adulterated with 28 per cent. of phosphate of lime; but it is believed that the salt made in the United States by the principal manufacturers is free from adulteration.

Citrate of Iron and *Quinine* is seldom found made strictly according to the U.S. formula, which does not produce a sufficiently soluble salt. Some manufacturers, therefore, add citrate of ammonia to make it soluble, and others leave out a considerable portion of the quinine to accomplish the same end. There is also a probability that in some cases cinchonine is substituted for the quinine.

Chloral Hydrate has been met with containing the alcoholate. The tests pointed out are the difference in boiling-point;* sulphuric acid, which leaves pure hydrate colourless, but turns alcoholate brown; and nitric acid, which gives little or no reaction with hydrate, but reacts violently with alcoholate, giving off nitrous oxide gas.

Chloride of Calcium has been noticed at Chicago with a large excess of caustic lime, and it is known to have been sold in crystals without any allowance made.

Chloroform is sometimes met with diluted with alcohol, and sometimes not sufficiently purified, and therefore unfit for inhalation. There is also reason to believe that partially decomposed chloroform has been sold through ignorance on the part of the dispenser. Nitrate of silver is useful in detecting this decomposition, by giving a precipitate of chloride of silver with the liberated chlorine.

Cream of Tartar is grossly adulterated, and the distinctive terms are said to be well known to mean varying proportions of terra alba and cream of tartar.

Epsom Salt has been substituted in the Western market by finely crystallized Glauber's salt. As the prices, however, are now about the same, this is not likely to recur.

Ether is sometimes sold containing a large proportion of alcohol. This may possibly arise from the druggist dispensing photographic concentrated ether, made to contain alcohol in order to dissolve the gun cotton.

Iodoform has been noticed of a light canary colour, a considerable portion being insoluble in ether; probably iodate of lime.

Acetate of Lead has been in the market containing a large percentage of crystallized nitrate of lead; one lot was offered to a maker of preparations for the hair as "damaged," which proved to be damaged sulphate of zinc, in lumps.

Precipitated Carbonate of Lime has been offered containing sufficient iron to give it a light fawn colour: supposed to be ordinary chalk, dressed.

Sulphate of Morphia is frequently open to suspicion. In one case the sample did not contain any morphia: placed on a red-hot plate it did not seem to lose any weight, and it was insoluble in water. A fraud in which sulphate of quinine was put into sulphate of morphia bottles has been lately detected in New York.

Phosphorus, according to Dr. Rademaker, sometimes contains arsenic.

Bromide of Potassium has been observed to contain a considerable quantity of water of hydration.

Iodide of Potassium is often adulterated with the bromide; some made in New York was found to contain carbonates in considerable quantity.

Sulphate of Quinine has many adulterants, among them, sulphate of lime; cinchonine, sold as "sweet quinine" or as "cincho-quinine"; muriate of cinchonine, sold as "light sulphate of quinine" and as "French quinine," salicine, etc.

Rochelle Salt has been offered for sale containing at least 25 per cent. of sulphate of soda.

Santonine was seen last year, in the New York market, contaminated with small particles of mica. This fraud may easily be detected by placing the suspected sample on a hot plate, the santonine will disappear and leave the mica.

Nitrate of Silver, made for the Government, was sold in Chicago, which contained five per cent. of copper. Pieces could be picked out emerald green in colour; it appeared to have been made by simply dissolving coin or other alloy of silver in nitric acid, and crystallizing without any attempt at purification.

Precipitated Sulphur is reported as usually free from sulphate of lime, and the United States pharmacist is congratulated on this superiority to the English article, but a proportion of 50 per cent. of gypsum in flowers of sulphur is reported as having been noticed, and sometimes ground sulphur is sold for the sublimed.

Tartar Emetic has been met with containing 11 per cent. of cream of tartar.—*Proceedings of the American Pharmaceutical Association.*

PRELIMINARY NOTICE OF SOME PRODUCTS FROM NATAL ALOES.

BY WILLIAM A. TILDEN, D.SC. LOND.

Nataloïn.

The aloïn of Socotrine aloes appears to be identical with that obtained from Barbadoes aloes, as they crystallize in the same manner, give the same colour reactions with oxidizing agents, and both furnish chrysammic acid by treatment with nitric acid. Natal aloes is a variety which contains a crystalline body of entirely different properties. This was examined for the first time by Flückiger,* and called by him nataloïn. It is readily distinguished from barbaloïn by its comparatively slight solubility either in water or in alcohol, by its crystalline form, and by furnishing, when acted upon by nitric acid, no chrysammic acid, but, as I have found,†

* Pharm. Journ. 3rd Ser., Vol. I. p. 87.

* Proc. Brit. Pharm. Conf., 1871.

† Pharm. Journ., New Series, Vol. II. 441.

picric in addition to oxalic acid. It contains no water of crystallization. Crystallized from spirit, and dried at 100° C., it gave me the following results:—

1.—0·5066 grm. burnt with a mixture of lead chromate and potassic dichromate gave 1·1070 CO_2 and 0·2775 H_2O.

2.—0·3715 grm. gave 0·8110 CO_2 and 0·1965 H_2O.

The percentages of carbon and hydrogen calculated from these data agree very nearly with the formula $C_{25}H_{28}O_{11}$.

		Theory.	I.	II.
C_{25}	300	59·52	59·59	59·53
H_{28}	28	5·55	6·07	5·86
O_{11}	176	34·92	——	——

They also approximate very closely to the average of the determinations made by Professor Flückiger, though the individual numbers quoted by him diverge very considerably from the mean.

Flückiger's Analyses of Nataloïn.

						Mean.
C	58·99	59·14	61·18	58·38	60·15	59.56
H	6·17	6·24	5·92	5.95	6·24	6·10

Acetyl-nataloïn.

Hitherto, although numerous experiments have been tried, I have found it impossible to obtain a chloro-bromo- or nitro-derivative of nataloïn.

When placed in contact with acetyl-chloride, a reaction commences almost immediately, and is complete after warming for a short time. The varnish-like residue left after chasing off the excess of the chloride and hydrochloric acid was dissolved in a mixture of alcohol and ether. In a short time, well-defined but microscopic crystals, consisting of rhombic plates and octahedra, were deposited. 0·143 grm. gave 0·307 CO_2 and 0·070 H_2O.

The percentages of carbon and hydrogen agree with the formula $C_{37}H_{40}O_{17}$.

		Theory.	Experiment.
C_{37}	444	58·73	58·54
H_{40}	40	5·29	5·38
O_{17}	272		

This formula is that of nataloïn in which 6H have been replaced by $6C_2H_3O$—

$$C_{25}H_{22}(C_2H_3O)_6O_{11}.$$

Action of Caustic Potash.

The products of the oxidization of socotrine aloes by means of caustic potash were studied some years ago by Hlasiwetz.* By melting this variety of aloes with caustic potash and a small quantity of water, dissolving the mass in water, acidifying with sulphuric acid, and agitating the whole with ether, an ethereal solution was obtained, in which two crystalline bodies were discovered. These were the para-oxybenzoic acid, $C_7H_6O_3$, of Fischer and Saytzeff, and α orcin, $C_7H_8O_2$.

Some Natal aloes was fused with potassic hydrate according to this method; the ethereal solution obtained left an aqueous liquid, and by continuing the distillation a small quantity of acetic acid passed over. On allowing the liquid to cool, a crop of well-formed colourless crystals was deposited; these, separated from the mother-liquor, were re-crystallized. They are only slightly soluble in cold water, and the solution possesses a strongly acid reaction. They melt at about 205° (the point was not accurately determined), crystallizing on cooling, and, when more strongly heated, volatilize with partial decomposition. Placed over oil of vitriol, they effloresced.

0·151 grm., dried at 100°, gave 0·3365 CO_2 and 0·065 H_2O. These data give percentages which agree with those required by the formula of para-oxybenzoic acid.

		Theory.	Experiment.
C_7	84	60·86	60·77
H_6	6	4·34	4·63
O_3	48	34·78	—

The mother-liquor from which these crystals were obtained was brown and syrupy; it was diluted, precipitated by acetate of lead, the excess of lead removed by exact precipitation by sulphuric acid, and the filtered liquid evaporated, first by the aid of heat, then *in vacuo*. A coloured syrupy residue was thus obtained, which gradually set into a crystalline mass. It was too small in quantity to attempt to purify further, but its reactions were carefully compared with those of the three known orcins.

For small quantities of β orcin and resorcin with which these experiments were made I am indebted to the kindness of Dr. Stenhouse.

A weak aqueous solution of each was employed.

(1). Orcin and resorcin with ammonia redden very slowly. β orcin and the new compound turn purplish red in a few minutes.

(2). With potash resorcin gives a green colouration; orcin becomes slowly reddish brown; β orcin and the new compound become rapidly purple, afterwards brown.

(3). A slip of deal, wetted with the solution, and then with hydrochloric acid, and dried, becomes, in the case of resorcin, blue; with the others a rich purple colour is produced.

(4). Aqueous chlorinated soda gives, with resorcin and orcin, a violet colouration which almost immediately changes to a dull green. With β orcin and the compound from Natal aloes an intense crimson colouration is developed, which is much more permanent than the violet produced by orcin.

(5). A portion of the syrupy solution, treated with concentrated hydrochloric acid and potassic chlorate, gave, in twelve hours, a crystalline chloro-derivative. There was not sufficient for analysis.

These experiments convince me that the orcin from Natal aloes is not α orcin; it is probably β orcin, or it may be the next higher homologue.

I very much regret that the small quantity of material operated upon did not yield sufficient of the substance to complete its purification. I hope, however, to confirm my opinion by further experiments and an analysis of the body.

The production of β orcin from a new and available source would possess considerable interest, as at present, in consequence of the uncertainty attending its preparation from usnic acid, from which alone it has hitherto been procured, its chemical history has been only imperfectly traced out.—*Chemical News.*

* Ann. d. Chem. u. Pharm., cxxxiv. 287.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A dinner to celebrate the success attending their first half-yearly session was held on May 9th.

Covers were laid for fourteen. Messrs. Branson and Osborne presided at the piano. After the usual loyal and patriotic toasts, the President, Mr. Masters, proposed the toast of the evening, "Success to the Northampton Chemists' Assistants and Apprentices' Association," which was drunk with musical honours. Among the other toasts proposed were "The Pharmaceutical Society, and A. Haselden, Esq.;" "The Pharmaceutical Journal, and Dr. Paul;" "The President, Mr. Masters;" "The Secretary, Mr. Druce;" "Professor Attfield;" "The Chemists of the Town;" "The Absent Members;" "E. Bremridge Esq.;" and "The Class-Takers."

The President said he was very much gratified to find they could display such an unusual amount of musical talent as had been shown that evening.

The Pharmaceutical Journal.

SATURDAY, MAY 25, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE JURIES BILL.

THE Government Bill on this subject which, as we announced last week, has now been read a second time, is one that, as a whole, seemed to meet with the approval of the House, although it contains some provisions which will doubtless provoke much discussion; such as one fixing the number of jurors in County Court cases at five, and in all other cases seven, except trials for murder, where the number is still to remain twelve as at present. It was, however, referred to a Select Committee, where the details will be considered and virtually settled.

But although so much has been gained, the Bill will require careful watching, since the extension of the exemption is so framed that, as pointed out by Mr. GILES at the Annual Meeting, the privilege at present enjoyed by pharmaceutical chemists is somewhat endangered. As will be seen by the quotation from the Bill given last week, the phrase "registered chemists and druggists" is the only one used in relation to persons on the Register; so that as the Juries Act, 1862, which exempts pharmaceutical chemists, is contained in the schedule of Acts to be repealed, should this phrase be cut out, it would have the effect of taking away the present exemption, unless some special provision were made. There is the more danger of this, because the extension of the exemption to registered chemists and druggists appears to be the only instance of the kind in the Bill, its general tendency being to curtail present privileges in that direction. There is also the other fact referred to by Mr. MACKAY, that since the Bill extends only to England and Wales, the Scotch members of the trade, whether pharmaceutical chemists or registered chemists and druggists, will still be liable to service.

Among the other matters worthy of notice, it is provided that a notice is to be sent by post to every man whose name shall be put for the first time upon the list of jurors, stating the time and place where objections will be heard, and informing him that he will not be excused from service on the ground of any exemption which shall not be claimed on such occasion. It is also provided that should a man be summoned who is by the terms of the Bill exempt from service, he may be discharged from serving upon challenge, or upon his own application, if the Court shall be satisfied of the fact; but no such exemption or want of qualification, if not submitted before such juror is sworn, is to be accepted as ground for impeaching a verdict given by a jury. Men of sixty-five years and upwards of age are to be exempt from service if the exemption be claimed in time, but at seventy years of age they become absolutely exempt.

NEW PHARMACY ACT IN PHILADELPHIA.

AN Act regulating the practice of pharmacy and sale of poisons, and to prevent adulterations in drugs and medicinal preparations in the city of Philadelphia, has recently passed both Houses of the Legislature. Stating in the preamble that the safety of the public is endangered by want of care in the sale of poisons; that the power of physicians to overcome disease depends greatly on their ability to obtain good and unadulterated drugs and skilfully prepared medicines; and that persons entrusted with their preparation and sale should possess a practical knowledge of the business and science of pharmacy in all its relations,—it enacts that no person shall hereafter open or carry on any chemical or drug store in that city, or engage in the business of dispensing medicines, or retail "drugs, chemicals, poisons or medicines," without having a certificate from, and being registered by the Pharmaceutical Examining Board. The Board is to consist of five skilled pharmacists engaged in business, appointed by the mayor, who are to hold office for three years, and to examine such persons as may apply to them for registration. The penalty for an unregistered person carrying on business is one hundred dollars per week; the penalty to be handed over to the guardians of the poor of the city. Persons in business at the time of the passing of the Act, and those holding a certificate from an incorporated college, are exempted from the necessity of examination, but not from registration. No person is to dispense prescriptions—except as an aid under the immediate supervision of the proprietor or a qualified assistant—who has not been apprenticed two years and attended one full course of lectures on chemistry, materia medica and pharmacy, and no proprietor is to leave his store in charge of any but a qualified assistant. There is also a clause enacting a penalty of five hundred dollars and forfeiture for knowingly, wilfully or fraudently falsifying or adulterating any drug or medicinal substance or preparation.

The Act appears to be received with approbation by the pharmacists of Philadelphia, although they would rather the appointment of the Board had been vested in themselves than in the mayor. That official, however, has shown a desire to carry out the Act in a proper spirit by requesting the college to nominate ten gentlemen from whom he might select the first Board; the gentlemen upon whom his choice has fallen being JAMES N. MARKS, C. L. EBERLE, JAMES T. SHINN, EDWARD PARRISH, and ROBERT ENGLAND.

There is no poison schedule to the Act.

HONOURS TO PHARMACISTS.

WE are pleased to be able to record, upon the authority of the *Hampshire Chronicle*, that the LORD CHANCELLOR has recently added to the Commission of the Justice of the Peace for the borough of Romsey, the name of Mr. W. H. SLATER, Pharmaceutical Chemist, of that town, and one of the founders of the Pharmaceutical Society. In France, MM. ROUCHER and COULIER, pharmaciens of the first class, have been nominated officers of the Legion of Honour; MM. MULLET, ROUCHETTE, and MARTY, pharmaciens of the second class, and MM. CATENAC and JOURDAN, holding the rank of pharmacien aide-major, have been nominated chevaliers of the Legion of Honour.

ARSENIC IN SULPHATE OF POTASH.

A CIRCULAR has been issued by M. BUSSY, Director of the Paris School of Pharmacy, stating that he has received information of a serious accident that has resulted through the sending out by a Paris wholesale house of sulphate of potash, containing a certain proportion of arseniate of potash, and recommending that no pharmacien should receive or deliver to the public any product that he may have received as sulphate of potash, unless he has previously ascertained that it is not contaminated with the arseniate. M. BUSSY offers the convenience of the laboratory of the School of Pharmacy for the examination of any specimens that may be thought to be doubtful.

A similar circular has also been addressed by the Minister of Agriculture and Commerce to the Prefects, requesting them to take steps to bring the subject under the notice of the inspectors of pharmacies, and to convey the information to the pharmaciens in their respective departments.

ON Thursday and Friday next, Dr. E. SYMES THOMPSON, Gresham Professor of Medicine, will deliver two lectures in Gresham College, Basinghall Street, the subject on Thursday being, "Prescriptions," and on Friday, "Mineral and Vegetable Tonics." The lectures, which will be illustrated by diagrams and experiments, are free to the public, and will commence on each evening at seven o'clock.

BY a decree dated March 15th, M. ERNEST BAUDRIMONT has been nominated Professor of Pharmacy and Chemistry at the École Supérieure de Pharmacie of Paris.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

A General Meeting of the above Association was held at the Rooms, on May 8th; J. D. SMITH, Esq., in the chair.

Before commencing the business of the evening, the CHAIRMAN read a letter from the local secretary, Mr. F. Sutton, expressing his regret at being unable to attend, and wishing every success to the recipients of prizes.

Mr. SMITH then proceeded to say that he felt great pleasure in being invited to attend, and occupy the chair on that occasion; and although it was his first appearance amongst them, it was not from lack of interest in the affairs of the association, but because he felt there were many members of more scientific attainments than himself. This led him to compare the advantages enjoyed by the young men of the present day, in being able to attend such an association as this, with those available during the earlier period of his life; and he would impress upon them that these increased advantages necessitated diligent application on their part, as the public demanded greater skill and more general knowledge in the profession; and he thought in the future they would still further extend their call for thorough proficiency. He then drew attention to the small attendance at classes, and said the absentees were doing themselves an injury, for if they failed to study during the years of their apprenticeship, they would find it very hard indeed to make up for lost time in after life. He wished them to compare themselves with those who had worked hard and whom they had assembled there that night to honour, and exhorted them to ensure a better attendance during the next Session. He held in his hand the reports of the various examiners for the Sessional Prizes, from which he gathered that although they were very well satisfied on the whole, they found the candidates somewhat deficient in the practical part; this he trusted they would endeavour to remedy.

The report of Professor Attfield, who had examine the papers for the Vice-President's Prize, was then read as follows:—

"Sir,—Five out of the six sets of answers to the questions for the Chemistry Prize do credit to teacher and pupils; the sixth candidate seems only recently to have commenced studying the subject.

"Assigning 100 as the full value of the answers, I have been able to place the competitors as follows:—

Mr. G. S. Tooke	78
Mr. H. A. King	63
Mr. H. A. Woolnough	58
Mr. S. R. Corder	55
Mr. J. Neale	53

"Yours faithfully,
"JOHN ATTFIELD."

Mr. SMITH then presented the prizes as follows:—

1st Prize	Mr. S. R. Corder.
2nd do.	Mr. H. A. King.
3rd do.	Mr. J. Neale.
Vice-President's Prize	Mr. G. S. Tooke.

The CHAIRMAN then said he should be happy to stimulate the efforts of the young men, and he thought he could not do better than offer prizes for best attendance at classes, but he should be happy to give them in any other way the Council might think more appropriate.

The President, Mr. A. HILL, thanked Mr. Smith in the name of the Association.

Votes of thanks to Professor Attfield for examination of the chemistry papers, and to Messrs. O. Corder, W. J. G. Butler, A. Hill, P. H. Mason, and F. Ellwood for undertaking the *vivâ voce* examination, were then passed.

Mr. O. CORDER, in returning thanks, said he had been much pleased with the progress made in botany by the respective competitors. He was better able to judge, as a twelvemonth ago he conducted the botany class. But while pleased with the theoretical knowledge shown, he noticed deficiency in describing the living plants he had placed before them. He thought that the neglect of the practical examination of plants was much to be regretted.

Mr. Butler then returned thanks, and also noticed the want of practical knowledge in pharmacy.

In proposing a vote of thanks to the Chairman, Mr. Cubitt wished to remind those present that it was scarcely to be expected that this association could undertake to impart really practical knowledge in chemistry and pharmacy. Both these subjects required a course of work in a laboratory, and he thought they ought to be satisfied with the evident proficiency shown by the candidates in the theoretical part. There was one subject certainly which the association seemed well prepared to teach practically, and that was Materia Medica; for, in looking round the rooms, he saw they were getting together a most excellent collection of specimens.

Mr. Butler seconded the vote.

After the Chairman had returned thanks, the meeting closed.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Half-yearly Meeting was held on May 8th. The chairman, J. Barry, Esq., J.P., opened the meeting by expressing his pleasure at being able to be present with them that evening, and said how gratified he was at the progress they had made. He pointed out the greater qualifications that were needed at the present time in a pharmacist, and how each should try to make himself master of the different subjects which the Pharmaceutical Society had to examine him in, especially as the tendency was to raise the standard of the examinations. He would suggest that French should not be lost sight of in their curriculum, as it would prove eminently useful to them in many ways. He then called upon the President to give his address.

President's Address.

I think, gentlemen, it will be as well for me to commence by taking a cursory glance at the proceedings that have taken place in connection with our Association since its formation, especially as it is our desire that our employers should be acquainted with all that has occurred, as it is through their kind and liberal aid that we have been able to make the satisfactory progress that we have.

The want of an association was very much felt by the assistants, more particularly by those coming to Northampton from towns where such an association existed, and by those who were anxious to pass their examinations.

Not a year ago the assistants of this town were scarcely upon speaking terms, and now I am happy to say there exists, with but one or two exceptions, an amount of friendly feeling that would render any service that one could afford another a matter of the greatest pleasure to perform. I mention this, gentlemen, to show that undoubtedly our Association has not been without good results apart from its chief object, *i.e.* educational purposes. After it was decided by the preliminary committee that an Association should, if possible, be formed, a meeting was convened, and our friend Mr. Law was asked to attend. He very kindly acceded to the wish, and the remarks that he made and the good advice he gave had a most beneficial effect; and I am sure it will be a long time before his sayings will be forgotten by those who were fortunate enough to hear him. The truth of one remark has often returned to my mind, that was, "When a person starts forward to do any good thing he will sure to find plenty to pull him back." Although we have felt the truth of that in a few instances, it is gratifying to know we have found those who were willing to aid us far outnumber those who would have thrown obstacles in our way, and so damped our ardour.

Our first difficulty was to obtain a suitable room, which was soon overcome by the kind offer of Mr. Jeyes in giving us this one free of expense; the next difficulty of furnishing it with table, chairs, etc., was quickly surmounted by the ready response made to the call upon our employers, and our last urgent want of apparatus and books has been supplied by the £10 grant from the Pharmaceutical Society, which I think we were most fortunate in obtaining, when we consider our Association has not been in existence more than six months, and other associations that have been in existence a much longer period have not been so favoured.

The source of instruction has hitherto been amongst ourselves, as we deemed it advisable to pass through the elementary portion of chemistry and botany before we solicited aid from other sources; but I hope that before long the Pharmaceutical Society will grant sufficient to deserving provincial associations to enable them to obtain the services of a qualified teacher (and I think that the best way they can decide upon to give help); by that means a good sound lecture could be heard once a week during the winter months at least. It cannot be expected that any gentleman who has the ability and is in business can afford the time to give a series of lectures, and very little information is obtained upon either chemistry or botany unless a whole course is gone through. However, if the Pharmaceutical Society will not supply us with funds to pay a teacher, I am happy to say there are two or three gentlemen who have promised us all the aid in their power, so between them I hope we shall be able to have a course of lectures upon one subject, at least that is when we find we must have higher instruction than our own resources can yield. I am very pleased to be able to state that the average attendance at the classes has been far above most associations that have sent their report to the Journal, as you will see in the Secretary's Report. I will just remark here that we are very fortunate in having a good secretary. It is well known that the prosperity of an association very much depends upon the efficient manner in which the secretary's duties are performed, and they are now done as well as could be if we had a paid secretary to do them. Besides being secretary, Mr. Druce is treasurer (not that that is very difficult, our exchequer being rather small), and he has the conducting of the Botany Class as well, which has been carried out most successfully; and in other ways Mr. Druce has been most energetic for the good of the Association.

I have seen in the Report of other Associations that they have games, such as chess, etc., and in one instance I noticed that they met to have a quiet pipe. Such doings I consider to be incompatible with study, and you will be pleased to hear, gentlemen, that neither one nor the other is permitted in this room; in fact, scarcely ten minutes is passed of an evening in any manner that does not in some way bear upon our profession.

Mr. Druce then read the following report:—

"The Committee have great pleasure in laying the half-year's report before the members of the Association, feeling certain that they cannot be otherwise than highly gratified at the position which it occupies, the great success which has hitherto attended its movements, and the estimation in which it is held by the principals in the town.

"The Committee beg to say that 23 members have joined the Association; three have left; so at present there are 20 members on their books, there being only 23 in the town. The average attendance at the classes has been 8. This attendance would, doubtless, at first seem small; but, on second consideration, it will be seen that it would not be possible for all members to get out on the same night, although willing to attend.

"The Committee earnestly hope that this attendance may not only be kept up, but, if possible, increased, as this is, after all, the great test of a society's usefulness and success.

"During the winter session nine classes have been held in Theoretical Chemistry, ten classes in Materia Medica; and the capital collection of official specimens has proved eminently useful in making the class a successful one. In Botany, twelve classes have been conducted, and the structural part explained. In Pharmacy, likewise, good progress has been made, questions having been asked on more than half the preparations in the Pharmacopœia.

"The Committee do not think they could continue with satisfaction the two classes weekly during the summer months, so have determined to have classes on one night only in the week—the classes to be botany and practical chemistry alternately, and one morning in the week to have a botanical ramble from 6 to 8 A.M. The Committee beg to draw notice to the success of the special meetings; nine have been held, and several subjects of importance discussed.

"The first was on October 26th, 1871, for the purpose of forming the Association; E. Law, Esq., J.P., in the Chair.

"November 27th, 1871, the first meeting in the new room lent by Mr. Jeyes; Mr. Bingley in the chair. Several points of great interest were brought forward, and the chairman gave them information which has proved very valuable.

"January 15th, 1872. For discussing the poison clauses of the Pharmacy Act, and the want of knowledge shown by coroners in their interpretation of the Act. It was recommended by the meeting that the Editor of the Pharmaceutical Journal should be asked to express his opinion on the particular case complained of, which request he was kind enough to comply with. The Committee are glad to notice that since that time the Council of the Pharmaceutical Society have ordered that a circular, explanatory of the Act, should be sent to every coroner in the kingdom.

February 14th. Professor Attfield, Ph.D., who had kindly consented to deliver some remarks explanatory of the examinations attended a meeting to which the Principals had been invited, and which proved in every way a complete success. "The Committee express their heartiest thanks to Professor Attfield for the extreme kindness shown on the above, and subsequent occasions.

"March 22nd. Mr. Lance read a paper on 'The Relation of Principals and Apprentices.' Mr. Osborne showed a variety of objects through a binocular microscope.

"April 8th. For the arrangement of the practical chemistry class, which the grant from the Council had enabled them to commence.

"April 25th. A paper by Mr. Masters on 'The Preparation of Tinctures,' and one by Mr. Druce on 'The Early History of Chemistry.'

"In regard to financial matters, the Committee beg to offer their sincerest thanks to the employers for the noble manner in which they responded to the application made to them.

"To the Pharmaceutical Society also they were under great obligations for their grant of ten pounds and for the Journal.

"The Committee also thank those assistants who have conducted the various classes during the winter session in such a satisfactory manner."

E. F. Law, Esq., J.P., after alluding to his not being in any way connected with the business to which the members belonged, in an eloquent address pointed out the advantages to be derived from studying science, the necessity for keeping their eyes open to the commonest affairs of life, for oftentimes great scientific facts were educed from the most common circumstances; and quoted several anecdotes to illustrate the truth of the statement. Referring to what the President had said about some societies having introduced smoking and chess, he strongly advised them not to copy the example, for however good they might be in their place, that place was certainly not the room the members met for scientific purposes in. It would never do for a student to begin analysis with a cigar in his mouth, nor to attempt to learn botany while playing at chess. The speaker concluded his interesting address amid the loud applause of his audience.

After a conversation relative to the formation of a Book of Prescriptions, the principals present promised all the assistance in their power to obtain some.

The Secretary then read the list of denatiens and the balance-sheet:—

RECEIPTS.

	£.	s.	d.
To Donations	13	9	0
,, Grant from Pharmaceutical Society	10	0	0
,, 22 Members' Subscriptions at 5s.	5	10	0
,, Allowance off Books		17	10
,, ,, ,, Bottles		2	0
	£29	18	10

,, Balance in hand	6	0	11½
	£29	18	10

Examined and found correct.

A. LANCE
H. LESTER } *Auditors.*
F. BRANSON

The President next alluded to the dinner, which would take place the next day, to celebrate their finishing the winter session.

Mr. BARRY said he would not disparage for a moment the dinner, which he hoped and expected would be a great pleasure to the members, but he would suggest that they should not be of too frequent occurrence; one every year, or every second year would be very suitable, but if they tried more they would find, instead of binding them together, it would have the reverse effect. He was much pleased with the action of the Pharmaceutical Society, and the members would do all, he was sure, to show that the kindness had not been expended in vain.

Mr. BINGLEY expressed a hope that a similar association might be formed by the employers in the town.

Votes of thanks to the Chairman and Mr. Law, and Messrs. Bingley, Clarke, and Ashford, were moved and seconded, and also to the President for his services during the session, concluded the meeting.

BRISTOL PHARMACEUTICAL ASSOCIATION.

On Friday, May the 10th, a General Meeting of the Association was held at the Bristol Library and Museum, on which occasion a lecture was delivered by WM. LANT CARPENTER, B.Sc., upon "Ocean Currents."

After proposing a hearty vote of thanks to the lecturer, the PRESIDENT reminded the members that this was the last evening lecture of the session, and that their next gathering would be upon the occasion of the Annual Meeting in July.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

At the rooms of the above Society, on Thursday evening, 16th inst., Mr. A. Anderson read a very interesting paper on "The Various Rhubarbs of Commerce." There was a numerous attendance of members, several of whom took part in the discussion which followed the paper; after which, a hearty vote of thanks was proposed by Mr. Bullus, seconded by Mr. Heslop, and carried unanimously. The meeting then terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, May 16th; Dr. Debus, F.R.S., Vice-President, in the chair.

The first paper read at this meeting was one "On the Influence of Pressure upon Fermentation, Part I.," by Mr. H. T. Brown; the results of his experiments being that, under diminished pressure, the amount of gas unabsorbed by potash is greatly increased, and that it contains a proportionally large amount of hydrogen. Acetic acid and aldehyd are also found under these circumstances, so that it would seem that water is decomposed during the alcoholic fermentation, especially when it takes place under diminished pressure.

Papers "On the Electrolysis of Sugar Solutions," by Mr. H. T. Brown; "On the Determination of Potassium," by Messrs. D. Page and A. D. Keightley, and "An Examination of the Recent Attack on the Atomic Theory," by Mr. Atkinson, were then read. The latter referred to Dr. Wright's paper on the Atomic Theory, recently read before this Society, and published in the April part of the Philosophical Magazine.

An animated discussion on the atomic theory ensued, in which Dr. Wright took part.

Mr. C. O'Sullivan then read his elaborate memoir "On the Transformation Products of Starch," and the meeting finally adjourned until Thursday, June 6th.

Professor Cannizzaro, of Palermo, will deliver the Faraday lecture "Sur les Limites et sur la Forme de l'Enseignement théorique de la Chimie dans les Universités," at the Royal Institution, on the 30th inst., at 8 o'clock.

PARIS SOCIÉTÉ DE PHARMACIE.

At the sitting of this Society on the 6th of March, under the presidency of M. Stanislas Martin, a paper that had been read before the Academy of Medicine by M. Hérard, advocating the use of tannate of quinine, gave rise to a discussion in which MM. Roucher, Poggiale, Bussy, Regnault, Bourgoin, and Petit took part.

M. Roucher said that the tannate was really efficacious, though less so than the sulphate, but that it could be employed with advantage in certain special cases.

M. Poggiale thought that it would be useful to determine first the composition and solubility of this salt.

M. Regnault said he had made some experiments in the preparation of this medicament. When acetate of quinine is treated with tannin, a turbid liquid is produced, which passes unchanged through the filter, and which it is impossible so to clear. This appears to show that the precipitate is very soluble in acetic acid; the addition of a little sulphuric acid, or even of sulphate of soda, leads to a decided separation. The tannate of quinine, well freed from sulphuric acid, is nearly insoluble in water, but soluble in alcohol.

M. Poggiale read an account of some researches of M. Cauvet upon rhubarbs.

M. Limousin read a paper on the preparation and purgative properties of sulphovinate of soda.

M. Bourgoin described a new process for the detection of adulteration of essence of bitter almonds by the so-called essence of mirbane, or nitrobenzol. He said that various methods had previously been indicated, but none of them had been quite satisfactory. The density of the nitrobenzol being greater than that of essence of bitter almonds, Vogel had proposed the estimation of the density of the suspected liquid. But the success of this test might be prevented by the addition of a sufficient quantity of alcohol, or other suitable liquid, to reduce it to the proper density. Dragendorff has recommended the addition of a globule of sodium to a mixture of a few drops of alcohol, and a small quantity of essence: colouration becoming more decided in proportion as the quantity of the adulterant is more considerable. Another process that would naturally suggest itself would be to distil the mixture in the presence of iron filings and acetic acid; to saturate the distillate with a little lime, according to Berthellot's method, and to develop a blue violet colour by means of a dilute solution of hypochlorite of lime. This test is a very delicate one when applied to pure nitrobenzol; but the presence of essence of bitter almonds singularly interferes with the reaction, and often only negative results are obtained with mixtures containing as much as 40 per cent. of nitrobenzol. M. Bourgoin proposes to treat a small quantity of the essence, about one gram, in a test-tube, with about half its weight of pure caustic potash, agitating it to favour the action of the alkali. If the essence be pure it will only assume a yellow colour, but if essence of mirbane be present, the yellow colour rapidly gives way to a reddish yellow tint, changing in less than a minute to a green colour. If then a small quantity of water be added the mixture separates into two layers, the lower yellow, and the upper green, which becomes red the next day. Alcohol does not interfere with these reactions; it seems, on the contrary to favour them, for the mixture becomes warm, and the green colour is rapidly developed.

M. Roucher said that he had prepared crystallized digitaline according to the process of M. Nativelle, as described by M. Buignet at the last sitting,* and that he had obtained very important results which he proposed to describe at a future meeting.

At the meeting on Wednesday, April 3rd, under the presidency of M. Stanislas Martin, a note was received from M. Pottier, of Auxerre, indicating a practical method for reducing alcohol to a desired inferior strength. The memoir was entrusted to M. Buignet for examination.

M. Bussy gave an account of the discussions that had taken place at the Academy between MM. Pasteur and Vergnette-Lamotte on the subject of the preservation of wines by the employment of heat.

M. Boudet referred to the following papers received by the Academy of Medicine:—(1) a note on Sydenham's laudanum, by M. Mayet; (2) a note on the same subject by M. Petit; (3) a memoir on the distribution of atropia in the belladona plant, by M. Lefort.

Upon the suggestion of M. Boudet, it was decided to appoint a committee to watch the proceedings of a committee appointed by the National Assembly for the purpose of investigating the subject of medical and pharmaceutical education on a proposition to concentrate the teaching of medicine at Paris.

M. Bussy called attention to a law recently passed by the National Assembly, enacting that the concentrated preparation known as essence of absinthe should only be made and sold as a medicinal substance, and that the commerce of the said essence, and its sale by pharmaciens, should only be carried on according to the legal prescriptions. He asked whether there were a tincture

* See *ante*, p. 865.

and an essence of absinthe in commerce beyond the absinthe of the liqueur dealers.

MM. Dubail and Adrian said that in the drug trade there was a considerable traffic in essence of absinthe, which preparation, with the addition of essence of anise, fennel, etc., served ordinarily for the manufacture of the absinthe liqueur, as the distillers rarely have recourse to the production of a true alcoholate. It was thought also that the names liqueur and tincture of absinthe were badly defined, and that it was necessary to settle this point before attempting to decide whether they ought to be considered as pharmaceutical preparations.

M. Petit said that he had been able to keep without sensible alteration dilute solutions (1 in 1000) of cyanide of potassium, cyanide of ammonium, and even of hydrocyanic acid. It was well known that cherry laurel water, which is a dilute solution of hydrocyanic acid, could be preserved without change for a long time, while a solution of one part in ten altered rapidly.

PHILADELPHIA COLLEGE OF PHARMACY.

At the Pharmaceutical Meeting of this Society, held April 16th, Professor Maisch presented the report of the Smithsonian Institution for 1870. The Professor also read a paper styled "Pharmacognostical Notes," which was referred for publication. Some remarks were made upon the use of Inula for hydrophobia, for which it has been asserted to be a positive cure.

Samples of an herb were exhibited by Professor Parrish, which is sold under the name of "wild tea," and used in cancerous affections. It does not appear to be the New Jersey tea *Ceanothus americana*. It was referred to Professor Maisch for examination.

Professor Parrish exhibited a sample of coated pills, sent from England, very handsome, but, as compared with sugar-coated pills, not so soluble.

Professor Maisch read a paper on the use of the volatile spirit of petroleum as a solvent for Oleoresins compared with Ether, which was referred for publication. Mr. Bullock remarked that some oleoresins were nearly insoluble in this spirit.

Professor Maisch detailed the result of his experiments on Monobromated Camphor, which he has succeeded in preparing without using hermetically sealed vessels, and thus doing away with the danger of explosions; a considerable quantity of hydrobromic acid is likewise obtained by this process, which, by the old method, was mostly lost. The experiments not being completed yet, the results will be communicated in detail at a subsequent meeting.

Mr. Boring exhibited a sample of purified suet, which was very handsome. It was made by treating the melted fat with table salt and alum, and after congelation, washing out the salts by large quantities of water; the re-melted fat is then benzoated. Professor Maisch stated that this was essentially the process employed by perfumers in purifying their fats for pomade.

SOCIETY OF ARTS.

April 24, 1872.

NUTS, THEIR PRODUCE AND USES.

BY P. L. SIMMONDS.

The subject on which I propose to address you may at first sight appear somewhat trivial and unworthy the notice of a scientific society. What is there, it may be asked, in nuts, of interest, commercially or scientifically, that merits attention or consideration which is not generally known? But I think, before I have concluded, I shall be able to remove any such superficial idea, and to show how large a part nuts play in commerce, and how important are the uses of their several products, as evidenced by the fact that we pay more than 3½ millions yearly for nuts and the products of nuts.

But first it is necessary to define what a nut is; and here I fear we shall meet with numerous conflicting opinions. In the popular sense of the term, it would probably be described as some seed, with a hard shell enclosing a kernel; but then chestnuts and other thin-shelled fruits vary the idea. The strict botanical designation would probably be a fruit consisting of a hard pericarp, surrounded by bracts at the base, of which the acorn and the filbert are examples. The seed-vessel, enclosed within an involucre or husk of the cultivated hazel-nut, is of the same nature as the cup of the acorn and the prickly case in which the nuts of the chestnut and the beech-mast are enclosed. Most probably my learned friend in the chair, if asked to define a nut, would state it to be synonymous with gland—an inferior, dry, hard, indehiscent, one-celled, one, or rarely two, seeded fruit. It is also applied to a superior fruit by some botanists, of a similar character in some respects to the above, as in the cocoanut. Nut is also applied to such fruits as those of labiate and boraginaceous plants, which are properly "achenes," and defined as a dry, one-celled, one-seeded, indehiscent fruit, with a hard covering. Willdenow's definition was, "A seed covered with a hard shell, which does not burst." N. Bayley's 'Dictionary,' revised by Dr. Scott, and published in 1764, defines a nut as "a fruit or kernel included in a shell, or a seed included in a brittle but not stony shell; if the shell and kernel are in the centre of a pulpy fruit, they then make not a nut, but a stone." But as I am about dealing with the subject commercially, and not botanically, I shall have to extend the range of definition very largely to take in all that are called nuts in commerce. The merchant and the broker are very lax in their designations; all, for instance, are *gums* to them, whether soluble, resinous, elastic, or mere inspissated extracts. So with many of the nuts of commerce, such as almonds, the seed of drupes, nutmegs, myrobalans, coquilla, cohune, candle-nuts, ground-nuts, *cum multis aliis*, which are not botanically nuts.

A variety of special dealers have certain so-called nuts in their trade.

The fruiterer and the Italian warehouseman have their edible nuts in cocoanuts, Brazil nuts, small nuts (Spanish and Barcelonas), cobnuts and filberts, walnuts, chestnuts, peccan and hickory, butter-nuts, sapucaya, pistachio, and cashew-nuts, seeds of the pine cones, besides the prepared *marron glacé*, candied, burnt, and sugared almonds, etc.; the grocer, his bitter and sweet almonds and nutmegs, his sassafras and Ravensara nuts; the oil broker, his ground-nuts, candle-nuts, palm-nuts, palm-kernels, oil nutmegs, bassia-nuts, and others; the turner, his coquilla, vegetable ivory, cohune, betel-nuts, and others; the druggist, his nux vomica, physic-nut, and cumara-nuts, or tonquin bean; the tanner, his nut-galls, myrobalans, also called gall-nuts in India, and bedda-nuts, valonia, or acorns and cups; even the coal merchant has his nuts, in a description of small coal so termed. Then there are hundreds of other so-called nuts which have limited but special uses, such as the marking-nut, the clearing-nut, the soap-nut, and the Bonduc nut.

To some of these nuts I propose directing your attention; and although it is somewhat difficult, from the varied uses of many, to strictly classify them, I will endeavour to throw them into a few groups which shall comprise, 1, the edible nuts; 2, the oil nuts; 3, the turnery nuts; and another group, which may include those of a miscellaneous character.

The following table gives an aggregate view of the value of our imports of nuts and their products for the latest year for which the official returns are published—1870:—

	Quantities.		Value. £
Almonds (sweet), cwt. ..	36,189	..	138,864
,, (bitter) ,, ..	7,618	..	20,966
Chestnuts, bushels......	31,767	..	22,108
Cocoanuts, No.	3,546,276	..	30,622

Small nuts, bushels	294,236	..	193,452
Walnuts ,, ...	152,681	..	42,638
Turnery and unenumerated nuts	-	..	42,972
Ground-nuts, tons	5,845	..	94,419
Other oil nuts, tons	18,033	..	231,123
Nutmegs, lb.	537,978	..	32,510
Palm oil, cwt..........	868,270	..	1,583,830
Cocoanut oil, cwt.	198,602	..	392,657
Coir fibre, tons	1,105	..	24,347
Cordage of ditto, cwt. ..	11,407	..	13,547
Cable yarn ,, ..	168,544	..	177,956
Myrobalans, cwt.	56,610	..	32,928
Valonia, tons	25,718	..	395,546
Nutgalls, cwt..........	17,748	..	54,169
			£3,524,657

EDIBLE NUTS.

The commerce in edible nuts of various kinds forms a considerable item, and furnishes a carrying trade of at least 10,000 tons. The average annual value of those sold amounts to upwards of £500,000. There are but five sorts specified in the official trade returns—almonds, chestnuts, cocoanuts, small nuts (hazel-nuts), and walnuts, but there are various other kinds forming articles of commerce in a minor degree, among which may be enumerated Brazil nuts, pistachio-nuts, cashew-nuts, souari and sapucaya-nuts, hickory and peccan nuts. Twenty years ago it was stated that the sale of filberts in Covent-garden amounted to 1000 tons in the year, and of walnuts, 25,000 bushels. Of the quantities grown in England there are no means of forming an estimate. The imports of nuts in 1848 were:—

	Bushels.
Hazel-nuts	150,022
Chestnuts	63,033
Walnuts	29,604

The progress of the import trade in these is shown by the following figures, from which it will be seen what a great advance has been made in the consumption of sweet almonds, walnuts, small nuts, and cocoanuts:—

	1855.	1860.	1870.
Almonds (sweet), cwt.	24,581	19,638	36,189
,, (bitter) ,, ...	7,366	7,361	7,618
Chestnuts, bushels........	64,756	25,218	31,767
Cocoanuts, number	2,217,350	2,479,251	3,546,276
Small nuts, bushels	243,458	198,563	294,236
Walnuts ,, ...	21,949	52,090	152,681

I now proceed to give a few details as to each of these kinds of nuts.—

Hazel-nuts are the fruit of the wild bush of *Corylus avellana*, unchanged and unimproved by cultivation. They seldom attain to any size in this country when left wild. The fruit differs from that of the domesticated varieties only in being smaller, while the tree is more hardy. The plant, which is a native of all the cooler parts of Europe, Northern Asia, and North America, is the parent of the many varieties of nuts and filberts now cultivated for their fruit. The trade in "small nuts," as they are termed in the official reports, does not vary very greatly in this country, perhaps 10,000 bushels more may be imported in one year than another. The maximum never exceeds 300,000 bushels. Of 294,236 bushels received in 1870, the bulk came from Spain, 14,000 bushels from Sicily, and about 11,000 from Russia, Turkey, and other countries. Their import value is from 10*s*. to 13*s*. 6*d*. a bushel. In commerce, though both produced by the same variety, *Barcelonensis*, the nuts are classed into two kinds:—1. The Spanish, which are the nuts coming from Gijon. They will not keep any time, and are said to be coloured by the dealers with the fumes of sulphur. They arrive in bulk in small schooners. 2. The Barcelonas, which are kiln-dried, and shipped from Tarragona to the extent of 8,000 tons a year, in bags of about 128 lb. In Russia and Turkey large quantities of fine nuts are produced of the Constantinople variety (*C. colurna*), which are roundish and very hard. 160,000 cwt. are annually raised at Trebizond and Kuirasond. The filbert has been referred to a distinct species, *Corylus tubulosa*. The term was originally applied to those kinds of nuts which have very long husks, and in which the nut is also of a lengthened shape; but owing to the number of varieties that have of late years been obtained, this distinction, which was never scientific, appears to be nearly disregarded, and nuts and filberts are almost synonymous terms, excepting that the wild, uncultivated fruit and those varieties which most nearly approach to it are never called filberts.

The best known varieties of the filbert are the white, the red, and the frizzled. The white is the kind most commonly grown in this country. In Kent many hundreds of acres are planted with filberts, for which the county is celebrated, and whence the London market is principally supplied. As much as 30 cwt. per acre has been raised on particular lands. When quite ripe, filberts will keep for several years in a dry room, and if the air is excluded, or the nuts placed in an air-tight jar, they will be sound and retain their flavour for an indefinite period. The hazel-nut yields about 60 per cent. of a bland oil, which is used by perfumers.

The cob-nut of Kent is a large, roundish, prolific variety—*grandis*—of the ordinary hazel-nut.

In almost every stage of its growth, the fruit of the walnut-tree is used. When young, green, and tender, walnuts are pickled and preserved with the husks on. About the end of June they may be preserved with or without the husks. When the nuts are fully ripe, which is generally at the end of September or the beginning of October, the kernel, deprived of its investing skin, is eaten in great quantities. As long as the skin can be easily removed, they are a nutritious and healthy article of diet; but when they get dry, so that their skins stick to them, they become indigestible.

The larger portion of the walnuts consumed in England are of foreign growth, and the imports are annually increasing; for whilst a quarter of a century ago we only imported 20,000 bushels, now we have come to require 153,000 bushels. The bulk of these come from France and Belgium, and small quantities from Holland and Italy. Their value is much less than that of small nuts, being only from 5*s*. 6*d*. to 6*s*. 6*d*. a bushel.

The albumen, which constitutes the bulk of the seed of the walnut, contains an oil which is used in large quantities, especially on the Continent. It is obtained by reducing the seeds to a pulp by means of a stone wheel and basin, and then expressing the oil, first without heat, and then by the application of heat.

In the provinces of the Peninsula where the olive does not grow spontaneously, and cannot be cultivated except in certain places having an equal temperature, as on the banks of the lakes, walnut-trees have been planted from time immemorial. They yield an oil which, when fresh, is used for food and lighting purposes, or for painting when it becomes rancid. In the north of Italy, in the valleys of the Alps, and also of the Apennines, the walnut-tree forms and gives its name to a special botanical region.

In Nassau and Switzerland this bland oil is much used, and is no bad substitute for olive oil in preparing salad. It is also expressed in Cashmere. The shells of the large kinds of walnuts are often mounted with hinges, as fancy receptacles for miniature articles, such as tiny wax dolls, scissors, thimbles, etc. The Limerick gloves are packed in walnut-shells, whilst rings, jewels, and other small presents are occasionally disguised in this rough case as an agreeable surprise.

Our trade in foreign chestnuts, the fruit of *Castanea* *vesca*, is not large, and has scarcely ever reached an import of 70,000 bushels. In the three years ending 1831 the average was 21,000, and they then paid a duty of 2*s*. a bushel. In 1842 the imports were 34,000 bushels. In 1855 the imports had advanced to nearly 67,000 bushels, but they have since fluctuated and declined. Of the imports in 1870 (31,767 bushels), about half came from France, and the remainder from Portugal and Spain. They are valued at 11*s*. to 17*s*. a bushel, those from the Peninsula being considered the best. The local consumption of chestnuts in France is said to be about six million bushels annually. In Spain, Corsica, and the North of Italy, they form an important article of food, and serve in a great measure as a substitute for potatoes and bread. The best are those which permit of being kept good for several months. This is done by preserving them in layers of straw or in sand. In parts of France and Corsica the fruit is husked and dried.

The kernel of the Tahiti chestnut (*Inocarpus edulis*), which is kidney-shaped, and about an inch in diameter, is eaten when roasted by the Pacific Islanders, and in New Guinea and the Moluccas. It is sweetish, but less pleasant than the chestnut, harder and not so farinaceous.

The large and handsome seeds of the Moreton Bay chestnut (*Castanospermum Australe*) are eaten by the natives in Queensland, but Europeans assert that they are hard, astringent, and not at all better than acorns. A good starch has, however, been made from them.

The almond is one of our important edible nuts of commerce. Prior to 1832, when the duty was reduced, the consumption of almonds, here, was only about 3000 cwt.; in 1836 it had sprung up to 8000 cwt., and now it has reached about 43,000 cwt., an evidence of the progress of commerce and the advantages of lower prices, for in 1839 the prices of the best Jordan were £9 to £10 per cwt.; Valencia, £4 to £10; and Barbary bitter, £2. 10*s*. Now the best Spanish are about £6. 10*s*.; other sweet kinds, £3 to £4, and Barbary bitter, £2. 10*s*. The imports in 1860 were 7361 cwt. of bitter almonds, and 19,631 cwt. of sweet almonds. In 1870 the imports of bitter were about the same, but of sweet the quantity was 36,189 cwt. The Valencia almonds are the largest and broadest in the kernel of any. The Jordans, which come from Malaga, are longer and narrower, with a more pointed kernel, about an inch long. The Barbary sweet and bitter are both small, irregular-shaped almonds. The Sicily almonds, although small, are larger and plumper than the Barbary.

The study of, cultivation, and commerce in almonds is one of considerable importance, for the fruit enters largely into domestic and other uses, forming a principal ingredient in cookery, medicine, and trade. The Provence almonds of France are soft-shelled, sold ordinarily in the shell. The "Princesses," consumed in France, Belgium, Holland, Germany, and Russia; the "Ladies," sent chiefly to the United States; wavy almonds, which keep the best, and realize double the prices of the ordinary varieties. These are principally used in confectionery, as burnt almonds, and for fine pastry. The bitter almonds are used in the preparation of liqueurs, macaroons, and different medicinal compounds. A bland oil is expressed from almonds, which is used in medicine. It is obtained alike from the sweet and bitter varieties, and is of the specific gravity ·915, of a pale yellow colour, but becomes colourless when long exposed to the light. It soon grows rancid. It is so plentiful, that 5½ lb. of almonds have yielded 1 lb. 6 oz. of oil by cold extraction, and ¾ lb. more on heating them.

The Brazil nuts of commerce, called castanhas in Brazil, are the seeds of *Bertholletia excelsa*. About twenty of these nuts are contained in cells, within a hard spherical capsule. They form a delicious fruit when fresh, and also yield a large quantity of oil. One pound of nuts will afford 10 ounces of a pleasant, bland, clear, yellow oil, which might be furnished in abundance to the markets of the world. It has a great tendency to change if kept, but is used for culinary purposes when fresh. About 90,000 bushels, valued at £36,500, are annually shipped from Para, and they arrive in bulk in small schooners. The first arrivals will often fetch about 42*s*. per barrel of 3½ bushels.

The nuts in the drupe of the *Pistacia vera* and its varieties, natives of Syria, are imported in small quantities here, shelled or unshelled. The pale green kernels have a flavour like sweet almonds, and are used as a dessert fruit in cooking and in confectionery. Although they are not now enumerated in the Board of Trade returns, in 1855 we imported 3210 cwt. of these nuts. The imports are, however, much less than this now. On the Continent and in Turkey pistachio nuts are much esteemed. From Aleppo the exports are about 1300 cwt. yearly. One of our large West-End perfumers (Piesse and Lubin) make large use of the pistachio nut in its meal, much recommended as a substitute for soap, pistachio-nut soap, and pistachio oil for the hair, which is said to be used in Spain for the raven tresses alike of the mountain peasant and the court beauty; and a powder and milky emulsion for the complexion are also made from it.

Pine seeds are an edible nut in very many countries. Those of the stone pine (*Pinus pinea*) are largely used at dessert with wine in Italy, under the name of pine nuts. They are brought to market at Lisbon, strung upon threads like beads, and suspended upon a girdle round the waist. The seeds of Lambert's pine, in North America, of Slave's pine, in Mexico, and of Gerard's pine, in Thibet and Affghanistan, are also eatable when fresh. In Switzerland the seeds of the Siberian stone pine are used in some places as food, and in others as an article of luxury. The shell being very hard, and requiring time and skill to separate it from the kernel, the doing so forms an amusement for some persons in the long winter evenings. The pinones of the imbricated-leaved pine of Chili are a chief article of consumption among the Indian tribes. As the seeds will keep long, they are often imported into the southern districts of Chili from the Cordilleras, and when boiled are eaten by the country people either hot or cold. The seeds are buried in pits by the Indians for winter use. Another species of *Araucaria*, whose fruit is called bunya-bunya by the natives, forms the principal article of their food in Northern Australia. The cone is very large, nine to twelve inches in length by nine inches in diameter. The seeds, which are readily shed, are from two to two and a-half inches long by three-quarters of an inch broad, sweet before they are perfectly ripe, and after that resemble roasted chestnuts in taste.

The seeds of the cones of *Pinus monophyllus*, of the Rocky Mountains, constitute the principal subsistence of some of the Indian tribes.

Parliamentary and Law Proceedings.

Sale of Vermin Poisons.

On Thursday, May 10, Mr. F. Price, coroner, held an inquest at Salford, concerning the death of Mary Hughes, aged 23 years, who died on Tuesday from taking some of "Gibson's Manchester Vermin Killer," which she had purchased at the shop of Mr. R. Duncalfe, chemist, Swan Street, Manchester, on the same day. The jury appended a recommendation to their verdict that greater restrictions should be placed on the sale of vermin powder containing poison. The coroner intimated that he had already communicated with the Pharmaceutical Society on the subject, and he would see that the suggestion of the jury should be forwarded to that Society and to the Home Secretary.—*Manchester Courier*.

Poisoning by Laudanum.

A case of poisoning was investigated by a coroner's jury at Kidderminster on Saturday, May 11th. A Mrs. Beames, the wife of a carpet weaver, had been in the habit of giving her child soothing syrup, and in a bottle similar to the one containing the syrup she had some laudanum. Intending to give the child some soothing syrup on the Wednesday, she accidentally took up the wrong bottle and gave it a dose of laudanum. The mistake was discovered an hour or two later and medical assistance obtained, but the child died. The jury returned a verdict that the poison was accidentally administered.—*Times.*

Poisoning by Carbolic Acid.

On Saturday, May 11th, an inquest was held at Maryport, touching the death of a carman, named Adams. It was shown that on the previous Thursday the deceased had been engaged in removing some furniture, and that while the cart was unloading he asked for some drink, and was told to go into the kitchen and help himself from a bottle of beer he would find there. It is supposed that in mistake deceased drank from a bottle containing carbolic acid; for, on returning, he complained that the beer was bad stuff. He soon became very unwell, and died the following day. While still sensible, he stated that he drank the poison out of the supposed beer bottle. The jury returned a verdict of accidental death from drinking carbolic acid.—*Carlisle Journal.*

The Jury System.

Among the gentlemen summoned to serve on the Grand Jury at the Central Criminal Court was Mr. Edward Thompson, a solicitor, who claimed exemption on the ground of his professional occupation.

The Court told him that, although he was legally exempted from serving by reason of his being a solicitor in practice, still, as he had allowed his name to appear in the jury list, the Court had no power to release him from serving. It was the duty of every one liable to be summoned under the new Jury Act to take care, if he was exempt, that his name was expunged from the jury list, for, if once the name was placed upon the list, the party was bound to serve.

Mr. Thompson was accordingly sworn upon the Grand Jury.—*Echo.*

[*⁎* A correspondent, in calling attention to the above case, points out that the ruling of the Court would apply to pharmaceutical chemists, so that it is therefore advisable for them at the proper time to examine the jury lists, to see whether their names are improperly placed theron, and if so to claim exemption before it is too late.—Ed. Pharm. Journ.]

The Shipping of Benzine.

On Tuesday, May 21st, at the Thames Police Court, George Curling, manufacturing chemist, of No. 17, St. Mary-Axe, City, was summoned before Mr. Lushington, charged with shipping a case of benzine without notifying the contents of the same by writing or in print on the outside of the case or box.

Mr. Charles Young, solicitor, appeared for the East and West India Dock Company, who prosecuted in this case.

From the opening statement of Mr. Young it appeared seven cases were sent from the defendant's premises to the Dock on the 9th of May. They were described and marked on the outside as patent medicine. The cases were shipped on board the ship Otago, lying in the Dock, on the 11th of the same month. One of the cases was afterwards found to be running, and upon opening it, it was found to contain benzine. The other six cases contained what they were represented to be, namely, patent medicine. There were four dozen bottles of benzine in the case, and on each of them that were labelled the benzine was described as being inflammable at 100 degrees of Fahrenheit. The ship Otago was bound to New Zealand, and called at Erith, down the river, to take a quantity of gunpowder on board. She also carried passengers that were going to New Zealand. The case ought either to have been marked on the outside relative to its contents, or else information should have been given to Superintendent Sheppy, of the Dock Company's own police, who would have seen that the box was properly labelled, and a description of its contents made known to the captain whom it was shipped with.

The defendant said an order was sent down to his firm for the shipment of various articles. It was an act of carelessness that the case containing the benzine was not marked describing its contents. He was totally unaware of the contents of the cases sent on board the Otago until he saw the bottle produced containing benzine.

Mr. Lushington saw no reason to mitigate the penalty, and find the defendant £20 and 12s. costs.—*Daily News.*

BOOKS RECEIVED.

A Manual of Chemical Physiology, including its Points of Contact with Pathology. By J. L. W. Thudichum, M.D. London: Longmans. 1872.

Air and Rain. The Beginnings of a Chemical Climatology. By Robert Angus Smith, Ph.D., F.R.S., F.C.S., etc. London: Longmans. 1872.

The Students' Pocket Companion to the British and London Pharmacopœias of 1851 and 1867. By George Barber, Pharmaceutical Chemist, Liverpool Sixth Edition, revised and enlarged.

Lecture Notes for Chemical Students. By Edward Frankland, D.C.L., F.R.S., etc. Vol. II. Organic Chemistry. Second Edition. London: John Van Voorst. 1872.

The Chemical Note Book: for the Use of Students. New Edition. London. S. Deacon. 1872.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 27. — *Society of Arts,* at 8 p.m. — "Silicates, Silicides, Glass and Glass Painting." By Professor Barff (Cantor Lecture).
London Institution, at 4 p.m.—"Elementary Botany." By Professor Bentley.

Tuesday, May 28. — *Royal Institution,* at 3 p.m.—"Development of Belief and Custom." By Mr. E. B. Tylor.

Wednesday, May 29. — *Royal Medical and Chirurgical Society,* at 8.30 p.m.

Thursday, May 30. — *Royal Society,* at 9 p.m.
Royal Institution, at 3 p.m.—"Heat and Light." By Dr. Tyndall.
Chemical Society, at 8 p.m.
London Institution, at 7.30 p.m.—"Experimental Evidence against the Spontaneous Generation of Living Things." By W. N. Hartley, F.C.S.
Gresham College, at 7 p.m.—"Prescriptions." By Dr. E. Symes Thompson (Gresham Lecture).

Friday, May 31. — *Royal Institution,* at 9 p.m.
Gresham College, at 7 p.m. "Mineral and Vegetable Tonics." By Dr. E. Symes Thompson (Gresham Lecture).

Saturday, June 1. — *Royal Institution,* at 3 p.m. — "Chemical Action of Light." By Professor Roscoe.

The "Profession of Pharmacy."

Sir,—I am glad to find Mr. Ellwood raises the question as to the correctness of the term "profession" as applied to pharmacy; and although it is one of no great importance, yet one often has one's sense of propriety violently offended by hearing some would-be professional using the term to his own magnification, while at the same time he has the least possible claim to it; but where ignorance is bliss, 'tis folly to be wise.

Pharmacy is a *quasi* science, and the practice of pharmacy, or the calling of a pharmacist, is like Mahomet's coffin, it is neither in earth nor heaven, but between both.

The term "profession" may be defined as the practice of any special knowledge for the good of the public, for a fee or honorarium, as distinguished from buying and selling, or payment by wage or salary; and honour is the corner stone of all honourable professions.

I do not deny that all pharmacists are entitled to use the term as applied to themselves, because there are many in our ranks who stand prominently to the front, and add to the practice of pharmacy other sciences, which they practise in every way as a "profession." But it is contemptible to hear the term abused in the way it often is, and applied to people whose culture is of the mildest type; and I echo Mr. Ellwood's concluding prayer, and join in his hope, that the day will soon dawn when pharmacy will be raised to its proper status and dignity.

F. M. Rimmington.

Bradford, May 11th, 1872.

Sir,—Pharmacy is at last assuming its proper rank as a branch of the medical profession. While it was open to all comers, a living out of pharmacy proper was impossible, consequently pharmacists became tradesmen. It is now so protected that it may gradually take its natural position, as in France and Germany. To promote the recovery of its true status, pharmacists should aim at a few special things: to encourage the discontinuance of dispensing by medical men, to relinquish prescribing, and to get rid, bit by bit, of that traffic in things not medicinal, which is the sole reason of its professional character being questioned. There is a course between presumption and depreciation, which the most modest pharmacists may now observe. They are members of a profession, and also tradesmen. They should claim the one appellation, and not disdain the other; but they should at the same time do all in their power to elevate the important calling to which they have devoted themselves, so that the next generation may not be critical when they hear it referred to in common parlance as "the Profession of Pharmacy."

Avalon.

The Social Status of Pharmacists.

Sir,—I have read with much pleasure Mr. Greenish's paper on "Pharmacy in Austria," and the discussion at the pharmaceutical meeting of the 1st instant, to which it gave rise. The issue of the latter seemed finally to limit itself to the question of the social condition of the trade in this country.

In a letter you did me the honour of publishing in November, 1869, I took occasion to observe, that, in my opinion, English pharmacists would take rank only in proportion as they eliminated from their wares such as form no part or parcel of their legitimate business, and I venture to regard the matter in the same light now as then.

Over-crowded, however, as the trade is at the present time, the prospect of attaining to especial distinction from among our fellow-shopkeepers by a commerce in things purely pharmaceutical, appears to me as remote as ever, since the adoption of the measure would involve on the part of the majority of our brethren neither more or less than pecuniary annihilation.

In Austria, Germany, and the States of northern Europe, I am aware that the apothecaries make a low estimate of the money value of materia medica, and of the skilled service required in their preparation, but the number of pharmacies being limited by law, the matter is counterbalanced by the fact that their practices are very considerable, and the amount of business transacted unusually large.

In Italy and France, where, to the best of my knowledge no restriction of the kind is in force beyond the provision that a man may not conduct two separate establishments (a provision easily evaded by working the second in another name), far higher remuneration is exacted.

The profession of pharmacy in these countries, however, in spite of the prevalence of good prices, and the social advantages enjoyed by those engaged in it, is not, broadly considered, in a prosperous condition.

The cause may be briefly referred to the fact that the *Pharmacien* or *Farmacista* holds it a duty to confine his pursuits to the immediate object of his calling, an exclusive principle undoubtedly prejudicial to his worldly interests in the face of so much competition.

With reference to ourselves, I quite agree with Mr. Groves—and the feeling he remarks may, I think, be traced from the time of Shakspeare to our own—that "it is customary to look down on pharmacists" who, although generally admitted to be an intelligent body of tradesmen, are somewhat contemptibly considered as a class whose "good" is borne on the "ill-winds" that scourge society at large, yet withal a struggling and impecunious section of humanity. To the ordinary English mind, this last failing is, I fear, an all-sufficient reason for their being held in low esteem.

While gratefully acknowledging the many important benefits already conferred on the trade by the protective influences of the Pharmaceutical Society, I would fain indulge in the hope of seeing still brighter days dawn on our efforts to emancipate ourselves from the old social ban.

Walter A. Powell.

Castle Street, Swansea, May 11th, 1872.

Emulsions.

Sir,—Mr. Rother, in his very practical Paper on the above, reprinted in your Journal of May 11th, has made known a perfect method of preparing an emulsion of turpentine with mucilage, hitherto, at the best, but an unsatisfactory performance; there is however, one point essential to ensure complete success, which has apparently escaped his attention, and that is the use of fresh mucilage. Following his directions, 2 drams of mucilage speedily emulsified $1\frac{1}{2}$ oz. turpentine, this with $\frac{1}{2}$ oz. of water produced a mixture containing two-thirds of its bulk turpentine; four days afterwards it still remains as perfect an emulsion as when freshly prepared, and promises to remain so. As a further test of its permanency, 1 dram of the mixture was diluted with 7 drams of water; after standing a few hours a "cream" only was thrown up, which may be perfectly reincorporated by shaking. I repeated the experiment, substituting sour mucilage for fresh, and found the trituration has to be continued for a much longer time; the emulsion is not so white, and though no actual separation of turpentine takes place on standing, still it is not near so homogeneous as when the fresh mucilage is used. What is rather surprising in this method is the remarkable property possessed by the mucilage of "killing" almost an unlimited quantity of turpentine. To ensure a permanent emulsion, a good deal of time and persevering trituration are necessary, combined with judicious additions of ingredients; and this is just one of those cases where a careful and discriminating operator will succeed, and the careless one make only a mess. This plan I find gives a result much superior to that detailed in the Journal of March 16th, by shaking powdered gum with turpentine, then adding the water, as this very soon separates into distinct layers of turpentine and water, and presents altogether an unsatisfactory appearance.

T. H. Hustwick.

Liverpool, May 18th, 1872.

Pharmaceutical Education in the Provinces.

Sir,—In your Journal of April 27th, I find a letter signed "A Country Major Associate," in reply to which I should like to say a word or two.

I quite agree with him that in provincial associations a very great difficulty is to find teachers, but that is no reason why they should not receive pecuniary aid from the parent society, but rather the contrary. Students in the country do not expect to receive instruction from duly qualified gentlemen for nothing; but if the parent society will give them no aid, they must either go without altogether or ask to have it gratuitously. The expense of going to London and attending Bloomsbury Square, does form a great barrier to hundreds of country students; but this "Country Major Associate" says that they had no right to enter the trade. Perhaps he has not yet learnt that the trade is free for any one to enter. Those who can afford to pay for high-class training will not enter the trade, as it will not pay for the large outlay required, while if the Society did its duty to provincial associations, there would be no necessity for country students to attend Bloomsbury Square. Provincial associations would be as much use to the country as the Square is to London, were they not crippled by want of funds. "Country Major Associate" seems to think £100 not too much for a course of chemistry, and that the teacher must be a high class professor with no end of degrees and diplomas. In most towns it would be difficult to find such an one, while the work would just as well be done by any gentleman who has passed the Major, for £20, and the same with botany, etc. I admit that provincial associations are greatly dependent on voluntary teachers; but this state of things is a disgrace to the whole community of chemists and druggists. "Country Major Associate's" reason for not spending £300 a year over provincial associations is rather a novel one,—as it is impossible to give £300 don't give any. I think the Society ought to give £100 a year to each of the existing associations, and surely it can afford this out of £10,000 a year. The Society gets at least £5 from each student, and is it not common honesty to give a little in return? I should think that in reviewing its past life, there is no act upon which the dying Council can look with so much satisfaction as its giving £48 out of an income of £10,000, to educate the pharmacists of the future. Is the revenue of the Society derived in the proportion of £9,950 from London, to £50 from all England? Besides, for the Society not to give aid to provincial associations is a proceeding fraught with the gravest danger to the Society itself. The rising pharmacists will grow up to look upon it with dislike as a Society which has done its best to thwart them in their efforts to educate themselves, and to rob them by exorbitant fees. Let it remember that the assistants and apprentices of to day will be masters in their turn, and take warning ere it is too late. Provincial members expect something for their subscriptions; they cannot attend evening meetings, or have access to the library, and naturally they expect some indirect good to themselves in the shape of help extended to their assistants and apprentices. We know what centralization has done for France; the Society, on the small scale, is doing as France did, and if an alteration is not made, and that at once, there will be the same result.

Judging from his letter, I should say, that "Country Major Associate" is one of those who look upon the business of a chemist and druggist as a profession, and pharmacy as a scientific pursuit for wealthy, learned gentlemen. I would venture to remind him that in nine out of ten cases, the proprietor has to get a living by his shop, not to pursue a scientific pastime, and that until surgeons leave off dispensing, the business of a chemist and druggist will be a trade, not a profession, and by no means a very profitable or pleasant one either.

G. T.

May 8th, 1872.

Sir,—Some few weeks since you were kind enough to insert my remarks on "Compulsory Education," and, amongst other matters therein stated, the education of apprentices was incidentally touched upon.

Since then, we have had in the Journal two, if not more, editorial articles, and several letters from leading chemists, almost entirely devoted to this subject.

Perhaps Mr. Atkins and Mr. Giles may be right in the main; but the latter, as the exponent of high class pharmacy, is not likely to bring over the great bulk of the trade to his views.

I believe we are most of us open to conviction; but, on the other hand, we object to being dragooned to meet other people's tastes and fancies.

Mr. Rimmington's communication contains many points well worthy of consideration, as also does the letter by a Country Chemist, "A Plea for Weak Brethren."

Being very anxious to ascertain the views of country chemists upon this important subject, I have taken advantage of every opportunity for discussing the question with them, and there seems to be very little difference of opinion upon the matter; we are all pretty well determined as to what we mean to do.

Now, before another word is said upon pharmaceutical education, let us take a glance at what is going on at the present day, in the higher profession of medicine. What do we see? Why in this town of 50,000 inhabitants, and in the villages round, there are many medical pupils; do the medical practitioners who take these pupils provide in their establishments dissecting rooms and museums for teaching them? No such thing! Are lectures and classes provided for them? Certainly not; the nearest medical school being between twenty and thirty miles from this.

Well, what do they do? Just this. Supposing they are wise and studious, and wish to get on, they avail themselves of every opportunity for study and for the acquiring of practical information. At the end of the term (we will take it for granted the Preliminary has been already passed) they go to London, or elsewhere, to attend hospital practice and lectures, and having passed their examination, they quietly settle down into a country practice.

Others, whose means are more ample, and who are ambitious of a higher standing, take the office of house surgeon, demonstrator, etc., fix themselves either in the metropolis or one of our large centres of population, and become great in their profession; and between these two classes there will always exist many different ranks and orders.

Now, apply this to the case of pharmaceutical pupils or apprentices. Speaking for myself, I intend to go on as we are now doing—to endeavour to select only such youths as have had a good education, and who appear to have an aptitude and taste for study, and who have the means necessary for defraying all reasonable expenses incidental to the requirements expected from them.

Of course proper arrangements will be made for allowing time for book study, and as far as circumstances will admit, and may be thought desirable, we shall make them acquainted with most of the ordinary pharmaceutical preparations; but what we shall not do is to take apprentices (as Mr. Giles demands) without calculating upon their doing any work, nor shall we turn our places into chemical laboratories, nor suffer ourselves to become laboratory teachers.

The facilities we offer will, we conceive, impart a good groundwork for further and higher instruction to follow. And to those who seek something higher and better, we must point out the Clifton sanctum, and other similar institutions, or as we conceive much better still, a short period of study in the Pharmaceutical School at Bloomsbury after they have concluded their apprenticeship.

The establishment of classes and lectures and other means for imparting knowledge should, by all means, be encouraged, but it seems to me most unreasonable that this should in any way be done out of the funds of the Pharmaceutical Society, particularly when so small a proportion of the trade is contributor to its funds.

If this sort of pampering goes on it will only cause a dissatisfied spirit to spring up amongst our young men. Instead of feeling that self-dependence which alone can give strength and vigour, they will be looking for help, first to this quarter and then to the other, and blaming everything and everybody but themselves as the cause of failure.

Let us do away with this paltry attempt at parading a pauperism which really does not or ought not to exist, and whatever plan for education may be determined upon, seek to make it self supporting.

I am convinced that two of the greatest sources of evil, with regard to the subject before us consists, first in the custom of taking youths as apprentices at too early an age, and secondly in their want of proper training during the time they are at school. The cure for the first is in our own hands. I would suggest that none should be taken younger than 16 years of age.

The second is not so easy to find a remedy for. For instance, I am seeking an apprentice. I apply to our principal schools, but cannot learn that those who have passed any of the examinations think of being chemists. I advertise, and from among other candidates I select one who has had three years' education at one of our Grammar schools, and finished off with two years instruction at a classical and collegiate school near London.

The printed report given him on leaving was of a very high character; but after two years with me and average allowance of three hours a day for study, I much question whether he could now pass the preliminary—partly owing to a bad system of school training, and partly, perhaps to carelessness and indifference on his part about the matter. My other apprentice has also had equal, if not higher advantages, but with not much better results.

The deficiency in school education seems to be, that the mental faculties are not properly called into play. Hence, although they can remember a good deal that has been committed to memory, they cannot write six lines correctly upon any given subject from their own composition.

It is as true now as it ever was that there is no royal road to learning; it is clearly patent to all who will open their eyes to see that, without patient toil and labour, no great progress can be made in any branch of knowledge or of art. But the youth who desires great things, aims at great things, and patiently strives after great things, humanly speaking, is almost independent of circumstances, and is sure to succeed; whilst, on the other hand, those who prefer spending the greater portion of their time in idleness and frivolity, cannot expect to make way; and they do not.

The truthful experience of a tolerably active life is this, that comparatively few of our young men care to give themselves the trouble to acquire those habits of thoughtfulness and patient perseverance without which a man had far better adopt some other sphere of labour than that of a chemist and druggist.

One Who Has Known the Drug Trade More Than Thirty Years.

The Alleged Poisoning at Newton.

Sir,—In your issue of May 11th a reference was made on the case of poisoning at Newton in which my name is brought into question, and it is said the woman took the powder in castor oil and was dead in half an hour after. This is quite incorrect, as she had not taken castor oil at all, and it is a question if she had any of the konsso. The powder was ordered to be taken in the usual way, to be followed with a dose of castor oil the following morning.

H. Brunt.

Hyde, May 13th, 1872.

[*** The report of the case was taken from a Manchester paper, but we do not see our correspondent's conduct is at all called in question, since the death was proved by medical and other evidence to have been caused by strychnia.—Ed. Pharm. Journ.]

The Preliminary Examination.

Sir,—In your last issue a correspondent calls himself "One who failed on April 8th." Allow me to state that his proposition, if practised, will be attended with good results. I am not surprised in the least that the Board of Examiners are dissatisfied with the results of the Preliminary examinations when there is too little time allowed to answer the twenty questions asked. Nine minutes per question is not sufficient when there are four translations and a piece of composition included in the questions.

Give us a fair thing and we will be satisfied. What do we want with Drapers' Measurements? as in the 11th question :—"How much cloth do we require for a cloak that has in it four yards of seven quarters wide of lining, the cloth being three quarters wide?" I am not aware that one out of the 21 young men who sat at Manchester answered that question, nor was there any candidate who had answered his questions before the time appointed to give up his papers.

Another who Failed on April the 8th.

A Warning.

Sir,—Permit me through the medium of the Journal to caution the London chemists against a "new dodge" as practised upon me, and I doubt not upon many others in this locality.

On the evening of Sunday, the 21st of April, a very plausible, and decently dressed young man entered my shop, and stated that he had come to London from Liverpool in order to obtain a situation in a London house, but had been quite unsuccessful, and was at that moment homeless and penniless, as his landlord had refused to admit him on account of arrears of rent. Upon my expressing some surprise that amidst the many advertisements in the Journal he had not found one to suit him, he replied that he was invariably objected to on account of his having come from the country. I, however, relieved his immediate necessities, and told him that I would write for him to a gentleman a little way out of town, whom I knew to be in want of an assistant, and if he called on Wednesday I would let him know the result. In answer to my letter, my friend at once telegraphed me to send him down, but as I did not take his address, and had told him not to call until Wednesday, I let the matter rest knowing that my friend would be in town on that day. Wednesday came, and so did my friend, to whom I introduced this very plausible and interesting individual, who at once accepted the situation, and gave us the address of a chemist in Liverpool to whom we were to apply for his character. Pending the reply from Liverpool, my friend took him to show him the way to the railway station, giving him a good meal as they went along. By-and-by back comes my plausible *protégé* saying that he had left my friend at the station, who not having any change had directed him to apply to me for any money he might want previous to his going to his new situation. This I at once refused to do, as my friend had not said anything of the kind to me, but I again gave him something to keep him afloat until the reply should come from Liverpool, and directed him to call again, upon which he left, looking rather dejected. In due time an answer arrived from Liverpool saying that he was utterly unknown to the gentleman to whom he directed us to write, and it is doubtless unnecessary for me to say that he never called again in order to know the result of our application for his reference.

Should this individual attempt anything of the kind upon any of your readers, I hope they will do as I shall do if he ever calls upon me again—show him the door.

James Richardson.

448, *Kingsland Road, May 1st*, 1872.

Dr. George Archbold.—Your letter was not considered fit for publication.

"*Nux Vomica.*"—The provisions of the Pharmacy Act do not apply to the drug in question; but its well-known properties should induce the chemist to caution the person to whom it is supplied, and it would be advisable to register the sale.

A. J. Rivett.—Your question is only susceptible of an answer similar to that which would explain why sugar is sweet.

A. Strachan.—Your letter has been handed to the secretary.

W. C. H.—Inquiries on the point shall be made, and the result communicated to you.

G. C.—Because the quantity of phosphate of lime ordered in Parrish's formula is twice that of the phosphate of iron.

"*Amateur.*"—A suitable work for consultation on the subject would be Dr. Reimann's work on 'Aniline and its Derivatives,' a translation of which, by Mr. Crookes, has been published by Messrs. Longmans.

H. Carr.—(1), Rutaceæ; (2), Canellaceæ; (3), Anacardiaceæ; (4 to 6), Burseraceæ or Amyridaceæ.

J. R. will find several recipes for cements in Beasley's 'Druggists' Receipt Book.'

A. Jones.—You will find the method of preparation described in most works on chemistry.

"*Student.*"—The formula for Parrish's syrup of the phosphates is given in the first volume of the present series, p. 857.

W. S. Bryant.—(1.) Yes. (2.) We are unable to inform you.

J. E. P.—(1.) Yes. (2.) We believe about three hours.

"*A Student*" (London).—You should apply to the Secretary.

"*A Victim who signs himself 'Beware!'*" writes to say that a person is going the round taking in people with an article called "Fire-proof Lustrine."

"*Cecil*" is referred to the rule as to anonymous communications.

Communications, Letters, etc., have been received from Mr. H. Pocklington, Mr. Heald, Mr. Lewin, Mr. Nockold, Mr. E. W. Howe, Mr. W. F. Smith, Mr. J. Davidson, Mr. G. Hindle, "One who would gladly be a Member," Interrogative," "Minor Triumvir," J. B.

SOME EXPERIMENTS ON SULPHITE OF MAGNESIUM.

BY R. H. DAVIES, BELL SCHOLAR.

Some discussion has recently taken place as to the composition and properties of sulphite of magnesium; I have, therefore, at the request of Dr. Tilden, undertaken a few experiments upon the matter.

Sulphurous acid gas, prepared by the action of copper on sulphuric acid, was passed, after being carefully washed, into water holding in suspension some ordinary carbonate of magnesium. The latter rapidly dissolved with effervescence, and the current of sulphurous acid gas was maintained until it appeared to be no longer absorbed, and the crystals first formed had re-dissolved, yielding a clear liquid. This solution was strongly acid to test paper; had a powerful odour of sulphurous acid, and, when shaken in a bottle, gave off that gas freely. A portion of this was submitted to analysis.

(1). 1·4175 grm., largely diluted with well-boiled water, required 56·45 cub. centim. volumetric solution of iodine (containing 1·27 grm. iodine in 100 c.c.)=12·74 per cent. of SO_2.

(2). 2·809 grms. required 112·8 c.c. of the same volumetric solution of iodine=12·85 per cent. of SO_2.

(3). 18·3695 grms., oxidized by means of potassic chlorate and hydrochloric acid, yielded 8·6665 grms. $BaSO_4$, corresponding to

2·3805 grms. SO_2, or 12·95 per cent. SO_2.

(4). 16·875 grms., treated with a strongly acid solution of $BaCl_2$, gave a precipitate weighing ·1412 grm., corresponding to ·230 per cent. SO_2. This existed as sulphate, and must therefore be deducted from the whole number found in the previous experiment. This will leave 12·72 per cent. of SO_2 existing as sulphite, and this result agrees closely with the numbers obtained by volumetric estimation.

(5). 19·539 grms. were evaporated slowly to dryness, and the residue strongly heated. It yielded 3·09 per cent. MgO.

The amount of sulphur found as sulphate would require ·14 of this MgO, leaving 2·95 per cent. combined as sulphite.

If this be combined as acid sulphite (or bisulphite) having the formula $MgH_2 2SO_3$ it will require 9·44 per cent. of SO_2, thus leaving 3·33 per cent. of gas free.

Summary of results.

	1.	2.	3.	4	Mean.
MgO......				2·95	2·95.
SO_2	12·74	12·85	12·72		12.77.

Ratio of MgO to SO_2 found = 1 : 4·32.

,, according to formula $MgH_2 2SO_3$ = 1 : 3·20.

It will be observed that the proportion of SO_2 to MgO is rather greater than would be required, supposing the solution to contain an acid sulphite of the formula $MgH_2 2SO_3$.

A portion of the above solution was slowly evaporated by simple exposure to the air. In this way crystals were deposited in about a week, which were found on examination to consist wholly of sulphate; oxygen had been absorbed from the air.

Another portion of the solution was evaporated at a gentle heat on a water-bath, and the deposited crystals collected, drained, slightly washed, and dried by exposure to the air. Analysed, they yielded as follows:

(1). ·3385 grm. required 31·3 c.c. vol. sol. iodine = 29·59 per cent. SO_2.

(2). ·2415 grm. required 22·5 c.c. vol. sol. iodine = 29·81 per cent. SO_2

(3). ·475 grm. gave on ignition ·089 grm. MgO = 18·73 per cent. MgO.

Summary of results.

	Theory.	1.	2.	3.	Mean.
MgO......	18·86.			18·73.	18·73.
SO_2	30·18	29·59.	29·81.		29·70.

The numbers in column headed "Theory" are those obtained by calculation from the formula of *neutral* sulphite $MgSO_3$ $6H_2O$.

The crystals sent to the museum by Dr. Archbold have precisely the same appearance as those analysed by me, and present the same reactions. They are neutral to test paper.

Dr. Tilden has furnished me with the numbers he obtained in the analysis of this specimen.

(1). ·207 grm. took 19 c.c. vol. sol. iodine =29·37 per cent. SO_2.

(2). ·506 grm. yielded ·096 grm. MgO = 18·97 per cent. MgO.

It appears from the above detailed experiments that the salt noticed by Dr. Archbold in the paper he communicated to the PHARMACEUTICAL JOURNAL a short time ago, is incorrectly described by him as the "Bisulphite of Magnesia," if by this name he wishes to indicate the acid sulphite of magnesium.

The formula of that salt, if procurable in the crystalline form, would be $MgH_2 2SO_3$, and not as he writes it Mg $2SO_3$.

But it has been already pointed out that it is highly improbable that such a compound can exist otherwise than in solution. It might as reasonably be expected that "Fluid Magnesia" would, on evaporation, yield crystals of the hydric or bicarbonate; but, as is well known, the crystals which are frequently met with in fluid magnesia are not bicarbonate, but simply normal carbonate, with three molecules of water of crystallization—$MgCO_3$ $3H_2O$.

In order to test further the possibility of producing crystallized bisulphite of magnesium, I intend to try the effect of exposing a saturated acid solution of magnesium sulphite to a low temperature. It is just possible that this compound, which I have shown cannot be procured according to Dr. Archbold's directions, may be obtained by this modification of the experiment.

EXTRACT OF MEAT.

BY P. MULLER,*

Docteur en Médecine de la Faculté de Paris.

Various concentrated preparations of meat have now for some years been used for the purpose of alimentation, and more particularly by medical men who have prescribed them in cases where the stomach has refused to receive ordinary food, or where they have sought to restore the powers of convalescent patients. The author, however, considers that there is considerable misunderstanding in reference to the properties of these extracts, and in the course of a lengthy memoir, from which we can

* Abstracted from a memoir by the author, published in the *Moniteur Scientifique*, vol. iii. p. 611.

only abstract the chief particulars, he endeavours to show (1) that the extracts of meat have no nutritive value, and (2) that they have a certain action due to the mineral principles—chiefly salts of potash—which they contain.

In the first part of his memoir, after glancing at some of the writings of Liebig and others upon this subject, Dr. Muller disputes an opinion of M. Poggiale, that broths and extracts are nourishing in proportion as they contain nitrogenous principles, and he lays it down as an axiom that their alimentary value depends on the presence of albumenoid matters capable of being transformed in the digestive canal into albuminose or peptose, which he considers to be the only nitrogenous aliment.

The usefulness of the extract of meat as an aliment has long been asserted on account of the nitrogenous compounds that it contains; but the author says that the fact has been lost sight of that this nitrogen is not in a state suitable for assimilation. He points out that the principal nitrogenous products present in extract of meat are creatine and creatinine, both of them crystalline substances.

Creatine ($C_4H_9N_3O_2+H_2O$) is a neutral body, which is changed into creatinine by the action of concentrated acids, through the elimination of water (Liebig).

$$\underbrace{C_4H_9N_3O_2}_{\text{Creatine.}} = \underbrace{C_4H_7N_3O}_{\text{Creatinine.}} + H_2O$$

Boiled for some time in a solution of baryta creatine breaks up into urea and sarcosine:—

$$\underbrace{C_4H_9N_3O_2}_{\text{Creatine.}} + H_2O = \underbrace{CH_4N_2O}_{\text{Urea.}} + \underbrace{C_3H_7NO_2}_{\text{Sarcosine.}}$$

There is also inosic acid ($C_5H_6N_2O_5$), a substance as yet little studied, to which is generally attributed the origin, during the changes which it undergoes in cooking, of the perfume of the meat. It has therefore probably a stimulating action.

With regard to creatine and creatinine, Dr. Muller refers to some experiments of M. Ritter, tending to show that they are not fixed in the system, but are immediately eliminated in the urine. To ascertain whether they might have an action similar to such substances as theine, cafeine, etc., in retarding the waste of tissue, the author undertook a series of dietetic experiments upon himself, using an increasing quantity of extract with both a normal and a vegetable diet; the conclusion to which he came being that they exercise no such power. He is therefore of opinion that the crystallizable nitrogenous principles contained in extract of meat have no nutritive value either directly or indirectly: not directly, since they are identical with the products of dissimilation that are carried off from the system with the excrementitious matter; nor indirectly, since they do not arrest the waste of tissue.

Dr. Muller then proceeds to estimate the value of various preparations by this test. As the result of an examination of several broths, prepared according to the formulæ of MM. Chevreul, Liebig and Beneke, he reports that neither of them contained more than one part of albumenoid matters to the thousand, a proportion which he considers to be of no service for the purpose of nourishment. But while disputing their usefulness according to the commonly accepted notion, he is of opinion that the aromatic principles, salts and condiments which they contain promote the secretion of the gastric juice, and so facilitate digestion. To this property he attributes the origin of the general custom of commencing dinner with soup, quoting the words of Brillat-Savarin, who says, in his *Physiologie du Goût*, that a soup is a light healthy diet, suitable to every person, which comforts the stomach and disposes it to receive and digest food.

Dr. Muller next passes in review some of the extracts of meat most commonly met with in commerce, and enters into considerable detail concerning their preparation and alimentary value.

The first mentioned is M. Reveil's meat jelly, made by boiling down to half its volume, over a moderate fire, and keeping carefully free from scum:

Beef muscle, minced and deprived of fat	500	grams.
Water	1000	„
Salt	3	„
Chloride of potassium	1	„
Carrots, turnips and leeks	30	„

50 grams of gelatine is then dissolved in it at a gentle heat, and it is run into moulds to cool.

M. Reveil claims for this preparation great virtues in restoring the strength of convalescents; but Dr. Muller considers that, being really only a mixture of broth and gelatine, it can yield nothing for assimilation.

In Frankfort, MM. Meyer-Beck and Ripps prepare what they call "Sirupus Extractus Carnis," of which 82 grams should contain the salts of 3 lb. of beef.* M. Hayer has analysed this preparation and says that it has nothing in common with extract of meat but the name, and that the albumen present is due to blood that has been added. He found—

Cane sugar	17·54
Albumen	3·95
Gelatine, phosphates and chlorides	9·49

The author considers that this analysis shows it to possess no nutritive value worth mentioning.

M. Reveil has proposed to replace this syrup by what he calls "Sirop de Musculine," made from—

Muscular part of veal, minced and deprived of fat	100	grams
Water	500	„
Hydrochloric acid	50	centigrams
Chloride of potassium	50	„
Chloride of sodium	50	„

This is macerated with occasional agitation for twelve hours, filtered, a kilogram of sugar dissolved in it at between 35° C. and 40° C., and water sufficient added to make up 500 c. c. of the liquid.

This preparation the author considers to be of scarcely more value than the preceding, M. Ritter having found upon analysis but 0·455 per 1000 of albumenoid matter.

M. Bellat prepares an extract by exhausting meat, chopped fine and free from fat and bone, with cold water until the liquor runs through uncoloured and insipid. The meat is then digested at a temperature of 90° C., with an equal weight of water and a proportion of bones, in vessels closed by strong covers fitted with safety valves, for six hours, during which time it is stirred by an agitator. It is then put in a hydraulic press, and the liquor, mixed with water and previously cooked peas, is added to the solution obtained by the cold operation, clarified by heating sufficiently to coagulate the blood, filtered,

* 'Pharmaceutische Central-Halle,' vol. iii. p. 297.

and the filtrate evaporated *in vacuo* to the consistence of honey. M. Poggiale reports that with 25 grams of this extract and one litre of boiling-water he obtained a savory broth having the flavour of that prepared directly from meat. This extract, however, is not much met with in commerce.

The Australian extract of meat is dismissed rather curtly, and an inferior sample appears to have been examined.

The next preparation referred to is that which is made in accordance with the directions of M. Liebig, by taking meat free from fat and bone, chopped small and steeped in its own weight of water, and raising it slowly to the boiling-point, the coagulated albumen being skimmed off. It is then pressed, and the liquid evaporated over an open fire to one-sixth of its original volume, and afterwards brought, *in vacuo* and at a rather higher temperature, to the consistence of an extract. M. Ritter says that this extract contains a small quantity of albuminose. He found—

Water	12·0
Organic matter	67·4
Inorganic matter	14·6

The organic matter consists of crystallizable principles not yet isolated and studied.

M. Hepp, principal pharmacien to the Strasburg hospitals, prepares an extract of meat by a modification of Liebig's process. The evaporation is not carried so far, and a fine jelly is produced which is flavoured with aromatic herbs. Upon analysis M. Ritter found—

Water	85·27
Organic matter	11·25
Inorganic matter.	3·48

This preparation, which contains 2·20 per cent. of albumenoid matter, and is taken without the least repugnance, the author considers to be superior to any of the preceding; but it is under the disadvantage of becoming quickly covered with mould, arising from the fermentation of the vegetable matter present.

In concluding this part of his subject, Dr. Müller refers to a statement by Baron Liebig, that one pound of his extract, with a sufficient quantity of potatoes and bread, would make an excellent broth for 128 soldiers. This the author disputes, saying that, though it would make a broth, the nourishment would not be so great as though the soldiers had the thirty-two pounds of meat that the pound of extract would represent. If extract of meat has any alimentation, he considers it to be due to the salts which constitute one-fifth of its weight. Of 100 parts of these salts, Baron Liebig says that 81 are soluble in water, and 19 insoluble, of which 5·77 is phosphate of lime, and 13·23 phosphate of magnesia. The extract may be beneficial at the termination of a long illness, since the saline matters principally necessary in the formation of the gastric juice are so furnished to the exhausted system. But as these are principally salts of potash, the extract will produce in the system the characteristic effects of those salts: in small quantity it is stimulant; but strong doses should be avoided, for then the salts of potash impede hematosis. M. Hepp found that the extract previously described as prepared by him was insufficient to support life in dogs,—one dying at the end of fifteen days, and one at twenty, and similar results were obtained by the author. But M. Kemmerich* has met with results that seem to point to direct toxic effects from the use of extract of meat alone. Two dogs were supplied by him, one with water only, the other with water containing five grams of extract, daily. At the end of ten days the latter, which had been the stronger dog of the two, could not walk, and on the twelfth day it died, after which time the former was restored to its normal food and recovered. During this time two other dogs were kept in good health by being fed upon the meat residue from which the extract had been prepared, seasoned with common salt. On another occasion death followed the injection into the stomach of a rabbit weighing one kilogram of the extract obtained from its own weight of meat. Dr. Muller does not, however, think that this toxic action is due to the organic crystalline principles contained in the extract, since a considerable quantity of creatinine has been injected into the blood of rabbits without any injurious effect; but that it is due to the mineral crystallizable principles—principally salts of potash,—M. Kemmerich having shown that the ash only will cause death.

The third and concluding part of the memoir deals with the physiological action of the salts of potash. It records an elaborate series of experiments as to the relative action of the alkaline salts upon the blood globule. It was found that the salts of soda retarded the decomposition of the blood globule longer than those of potash and ammonia, and that they also retained a larger proportion of oxygen. In the presence of potash salts, it was found that the globule absorbed less oxygen, and the serum less carbonic acid. The author is, therefore, of opinion that too large a quantity of extract of meat, administered at the close of a long illness, when the system is exhausted by a long abstinence, would be injurious in proportion, as the organism has lost its chloride of sodium, and that the medical man should be aware that to give these extracts alone is but to prolong the feebleness of his patient.

* 'Wiener medizinische Wochenschrift, 1869.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Concluded from page 947.*)

XII. Adulterants.

This series of papers would scarcely be complete without an enumeration of those insects which from time to time have been found mixed up chiefly with the commercial Cantharides, as an adulteration, not possessing in themselves any vesicating properties. In all these cases it may fairly be presumed that the mixture was compounded with a fraudulent intention.

The largest and most attractive of these insects is the Green Musk Beetle, *Aromia moschata*, L., the *Callichroma muscata* of Moquin-Tandon, and *Callichrôme musqué* of Guibourt, figured in Curtis's 'British Entomology,' plate 738. It is one of the *Longicornes*, from 1 inch to upwards of 1½ inches in length. The following is its technical description:—Shining green, coppery, or bluish; glabrous; head slightly punctured; thorax irregularly tuberculated; elytra thickly roughened, especially at the base; with three faint varied hairs; legs and antennæ bluish. It is found on willows, being a common European species, and not uncommon in Britain. When employed as an adulterant, of course the long horns are broken off, and, indeed the elytra are the chief parts used, which it need scarce to be said contain no vesicatory properties.

Moquin-Tandon mentions also the common Rose Chafer, *Cetonia aurea*, L., the *Cétoine dorée* of Guibourt, as one of the insects which are mixed with the Cantharides for the purpose of fraud. It is abundant on flowers in many parts of Britain, and is thus described:—Shining golden green or deep black; beneath, bright copper; head and thorax punctured; scutellum smooth; elytra irregularly punctured, the suture and three lines faintly elevated, the apical portion with several waved whitish scales and spots; sternum with its tip somewhat globose. When fraudulently employed it is also broken up, or the very different shape would instantly be recognized. In colour it very nearly assimilates to that of the 'Spanish Fly,' or Cantharides of commerce.

The species of *Chrysomela* alluded to by Moquin-Tandon is probably the same as that exhibited in the Museum of the Pharmaceutical Society, and which is a plump little green beetle, picked out in some quantity from a sample of Cantharides which was imported into London. This is the *Chrysomela graminis*, L., figured by Donovan in his 'British Insects,' plate 365, fig. 1. Oblong-ovate, convex, shining blue-green; head and thorax thickly punctured; elytra thickly and finely punctured, punctures distinct and irregularly placed in lines towards the sides, surface of a uniform blue-green; legs and antennæ brassy green. Found in grassy places in many parts of Britain. It is not improbable that *Chrysomela fulgida*, Fab., is sometimes mixed with it.

The remaining species cited by Guibourt are *Diphucéphale soyeux*, figured in the Atlas to the 'Règne Animal' of Cuvier, plate 43, fig. 3; the *Mélyre vert* or *Melyris viridis*, Fab., figured in the same work, plate 32, fig. 18; and *L'Euchlore de la vigne*, or green vine beetle, *Bromius vitis*, also figured in the Atlas cited, plate 43, fig. 7. All these green beetles, and probably others of the same colour, have been broken up and mixed with the officinal Cantharides. It is easy for an entomologist to detect these fraudulent mixtures even from the fragments into which they are broken, especially by the use of the microscope. None of them possess vesicating properties in the smallest degree, and it is believed that the readiness with which such adulterations can be detected, is one of the chief reasons why the fraudulent adulteration of Cantharides is not practised to any important extent; in fact, it seems difficult now-a-days to meet with a sample of the adulterated drug.

THE USE OF PETROLEUM-BENZINE* IN MAKING OLEO-RESINS.

BY JOHN M. MAISCH.*

Petroleum benzine is an excellent solvent, and has been repeatedly suggested for introduction into the pharmaceutical laboratory, particularly when, in consequence of the high tax upon alcohol, the price of ether and the other derivatives thereof was even higher than at present. It is not unlikely that the so-called benzine may have been substituted wholly or in part for ether before experiments on this subject were published.

In 1866 Professor Procter* proved that cubebs, after having being exhausted by the solvent in question, yielded to ether over 4 per cent. of cubebin, waxy matter, chlorophyll, with a little pungent resin. Mr. H. N. Rittenhouse† therefore suggested to prepare oleo-resins by employing first ether, and finish the percolation with petroleum benzine. In 1867 an interesting discussion on this subject took place at the meeting of the American Pharmaceutical Association,‡ but the facts at that time published were very few in number.

At the close of the last session of the Philadelphia College of Pharmacy two essays were presented, both treating of this question from a different standpoint, without, however, exhausting it. Notwithstanding this, the results are sufficiently interesting to deserve notice. Mr. Alfred H. Bolton treated powdered capsicum, cubebs and ginger with petroleum benzine, spec. grav. 700, and exhausted them by the process of repercolation, whereby the powders were left entirely or almost tasteless; three troy ounces of the powders named yielded respectively six, four, and one fluid drachms of oleo-resins.

Mr. Milton W. Roth operated on ginger and cubebs, and observed that these substances, when exhausted by petroleum benzine, spec. grav. 686 to 710, would again yield to ether some non-volatile matter, which it is to be regretted was not sufficiently examined; the benzine oleo-resins of both drugs were perfectly soluble in ether, but the ethereal oleo-resins yielded precipitates on being mixed with benzine. It follows conclusively from these experiments, what Prof. Procter (loc. cit.) proved in 1866 for cubebs, that the benzine oleo-resins are not *identical* with the officinal ethereal oleo-resins, while Mr. Bolton, from the tastelessness of the residuary powder, argues or rather is inclined to regard the two products as representing the drugs in question.

The absence or presence of odour and taste, however, are too unsafe criteria of the medicinal properties, since some decidedly active principles, like santonin, the resins of jalap and scammony, etc., are tasteless or nearly so, while the experiments of Dr. Bernatzik,§ Mr. F. V. Heydenreich,|| and of E. A. Schmidt,** prove that the volatile oil of cubebs has no diuretic properties whatever, but acts as a carminative, diffusive stimulant and irritant, like most other volatile oils.

Petroleum benzine is such an excellent solvent, and at the same time so low in price, that its employment in the place of ether and even alcohol is very desirable; but from all the knowledge we possess thus far, based upon critical experiments, the substitution of the liquids in question for pharmaceutical preparations must be regarded as inadmissible until it has been proven that the proximate principles not acted upon by the benzine are medicinally inert; odour and taste alone are insufficient to furnish this proof.—*Amer. Journ. of Pharm.*

* The application of the term benzine to this volatile spirit is objectionable, inasmuch as it is liable to cause misunderstanding. It is the more volatile portion of petroleum or paraffin oil, and would be better designated petroleum or paraffin naphtha.—ED. PHARM. JOURNAL.

REMARKS ON PLANTS FURNISHING VARIETIES OF IPECACUAN, AND ON THE CULTIVATION OF CEPHAELIS IPECACUANHA (RICH.) IN THE ROYAL BOTANIC GARDEN OF EDINBURGH.

BY PROFESSOR BALFOUR.*

(*Concluded from page* 949.)

The people who gather the Poaya (Ipecacuan) are called *Poyaeros*. When gathering the plants, the Poayero seizes several stems with one hand, while with the other he pushes into the ground obliquely a sharp-pointed stick called *saracoa*, by means of which he raises up the roots. He then pulls up the plants with their loosened roots. The Poayero then separates the roots, removes the adhering earth from them, and puts them in a bag which he carries suspended at his side. A skilled collector can pull up, in the course of a day 15 kilogrammes (about 30 lb.) of Ipecacuan. In general, however, the quantity collected in a day does not amount to more than from 3 to 5 kilos, *i.e.*, 6 to 10 lb.

The Poayero gives the roots to a superintendent, who weighs them, and lays them out to dry. The more rapid the drying so much the better. Hence, the process is best carried on in full sunshine. In favourable weather the roots are dried in the course of two or three days. The process goes on more rapidly when the roots are protected from the night dew. When properly dried, the roots break easily with a resinoid fracture. The gathering of the Ipecacuan goes on during the year, but in general it is intermitted during the rainy season.

The flowering of the plant takes place in the months of February and March. The plants by being pulled up are often prevented from producing seed; they, however, propagate readily by buds from the creeping rhizome. The parts of the roots from which the buds spring are shown in the plate illustrating Mr. M'Nab's paper (Trans. Bot. Soc. vol. x. plate iv.)

When the Poayero pulls up the roots, he breaks them at certain points, and from these ruptured parts young plants proceed, and thus the total destruction of the plant is prevented. In Matto Grosso, Weddell says that the Poayeros take some pains to protect the part of the roots left in the soil, and fill up the holes when the plants have been pulled. In this way it is probable that in the course of three to four years the ground which has been robbed of plants may recover itself.

Dr. Gunning, however, in writing to Dr. Christison, from Rio Janeiro, says, that in that district, the plant is extensively destroyed by the operations of the Ipecacuan gatherer, and that in the course of time it becomes scarce, and altogether disappears in the searched localities. Hence the necessity for planting Ipecacuan in places where it can be protected, the collection of the roots being put under proper superintendence.

Weddell thinks that the burning of the forests in Brazil rather tends to propagate the plant. Before burning, the soil is encumbered with a great amount of vegetable débris, which accumulates to such an extent as to prevent the seed of the Ipecacuan from falling into congenial soil, and to choke any plants which may be in a growing state. The burning of the forests acts in removing this débris.

When the roots are properly dried, they are broken into small fragments. From 1835-37, Weddell says that in the neighbourhood of Villa Maria (in Upper Paraguay) 150,000 kilos. of Ipecacuan were gathered, and there were from 1200 to 1500 collectors in the forests. Men, women, children, free people, and slaves, went into the depths of the Paraguayan forests, and spent some months in collecting the roots. At that time, the price of 14½ kilos was 50 to 60 francs at Villa Maria, and 78 to 90 at Rio Janeiro. This state of matters, however, soon ceased, and the Poayeros took to the usual plan of collecting.

The first figures of Ipecacuan were given by Piso and by Marcgrave, but evidently from the same drawing. It was not, however, such as to enable botanists to determine the plant.

Ray believed that Ipecacuan was furnished by a species of *Paris*; Morison, Plukenet, and Linnæus referred it to *Lonicera*. At that time, all annular emetic roots were called Ipecacuan. The drug of commerce was heterogeneous, and was supplied from various sources. The specimens were long distinguished by the colour; and we had brown, grey, black, and white Ipecacuan. In 1764, Mutis, Director of the Botanical Expedition to Santa Fé de Bogota, in New Granada, sent to Linnæus specimens of the plant which furnish the Ipecacuan root of that country. In 1781, Linnæus the younger described the plant under the name of *Psychotria emetica*. In 1800, Bernardo Gomez, a Portuguese, gave an accurate scientific description of the Ipecacuan plant; and on the 3rd of February, 1801, his countryman, Felix Avellat Brotero, Professor of Botany in the University of Coimbra, republished his description, without acknowledgment, in the Transactions of the Linnean Society (vol. vi. p. 137), and called the plant *Callicocca Ipecacuanha*. The genus was described as having an ascending, somewhat shrubby, creeping stem, with ovate-lanceolate leaves, somewhat pubescent on the lower surface, a terminal pedunculate capitulum of flowers, a four-leaved involucre, with subcordate leaflets, and a 5-cleft corolla. He considered this the plant of Piso, and gave a full description of it, with an excellent figure. It was found in Pernambuco, Bahia, Rio Janeiro, San Paulo, Marian, and other parts of Brazil. Achille Richard agreed with Brotero in regard to the plant which yielded the true annulated Ipecacuan. It was, however, referred by him to the genus *Cephaelis* of Swartz, as given in his 'Prodromus Floræ Indiæ Occidentalis.' The plant is placed in the Natural Order *Rubiaceæ*, Suborder *Cinchoneæ*, or, according to Lindley, the Order *Cinchonaceæ*.

The following are some of the genera of the *Cinchonaceæ* which contain plants used as Ipecacuan:—

A. Fruit with 1-4 seeded loculaments.
Cephaelis, *Psychotria*, *Richardsonia*, *Borreria*.

B. Fruit with many-seeded loculaments.
Manettia.

Besides these, we also find plants known by the name Ipecacuanha in other Natural Orders, as already mentioned.

Let us notice some of these plants.

Cephaelis.—Calyx-tube obovate, limb very short, 5-toothed; corolla somewhat funnel-shaped, with five small, rather obtuse lobes; anthers included. Style usually long,* with an exserted bifid stigma. Berry obovate-oblong, crowned with the remains of the calyx, bilocular, two-seeded. Shrubs or herbs, with oval, acute, petiolate leaves; stipules, 2-toothed and partite. Capitula terminal or axillary, with 2–8 bracts.

C. Ipecacuanha.—Stem ascending and afterwards erect, somewhat pubescent at the apex, leaves oblong-ovate, rough above, with slender pubescence below, stipules cleft in a setaceous manner. Capitula terminal, stalked, erect, and afterwards pendulous. Root creeping, annulate, brown or grey in colour. It is known as Ipecacuan in Europe, and as one of the Poayas in Brazil—annulated Brazilian or Lisbon Ipecacuan of commerce.

One character is omitted in the description, viz., the clusters of oblong, somewhat ovate glands, which are found on the inside of the stipules at their base. There are stomata and hairs on the epidermis. The stomata are deeply situated, and are surrounded by a series of epi-

* Read before the Botanical Society of Edinburgh, May 11th, 1871

* Martius says style equals length of corolla tube in *Cephaelis*.

dermal cells. The hairs are conical, and arise from a series of 5-7 cells at the base. They are often partitioned. The section of the aerial stem shows a cortical, fibrous, and medullary portion. The epidermis consists of condensed cells. Below it are cells more or less hexagonal. Then we come to the vascular circle, consisting of spiral and pitted vessels, and fusiform tubes of wood. In the centre are the hexagonal cells of pith.

The true Ipecacuan of commerce is an annulated root, occurring in pieces three to four inches long, and about the size of a small writing quill, variously bent. The rings constitute the cortical portion of the root. They can be easily separated from the central portion, and pulled off in a ring-like shape. In many pharmaceutical specimens the hard central part is seen between some of the rings. They appear like a row of rings strung on a fibrous hread; hence the name ringed or annulated.

The root has a resinous fracture. The outer portion is of a dark brown or grey colour. The epidermal portion consists of compact cells. Below these are hexagonal cells, full of starch grains of various forms—round, oval, and angular, with a distinct hilum, which is round, or angular, or elliptical. Near the hilum there is a dark shading, which seems to indicate striation. Neither Mr. Sadler nor myself have been able to detect true striæ on them, even under a Ross microscope magnifying 870 diameters. In some of the cells, the starch grains are crowded together so as to fill the whole cavity.

The inner part of the cortex consists of more delicate and more transparent cells without starch, or, at least, with a small number of grains. Then comes the central part, called by pharmaceutists the meditullium. It is of a fibrous nature, and consists of pleurenchyma and pitted vessels without any spirals. These vessels are arranged in wedge-shaped clusters, radiating from the centre. In some of the tubes of the wood starch-grains are found in large quantity. There is no true pith. From the meditullium extend spur-like processes, which are rudimentary buds. When the root is cut into pieces, these projecting portions constitute the nodes whence buds proceed. It is by means of them that plants have been propagated.

The cortical part of the root contains the active principle called emetine or emetia, which was discovered by Pelletier and Magendie in 1817. It is a white, slightly bitter substance, is insoluble in water, or ether, but is soluble in alcohol and dilute acids, as well as in chloroform. In the dose of one-sixteenth of a grain it acts as a violent emetic. Two grains of emetine will kill a dog.

One of the plants early used as Ipecacuan, and figured as such, under the name of striated, black, or Peruvian Ipecacuan, is *Psychotria emetica*. It differs chiefly from Cephaelis in the want of the common involucre, and in the flowers being stalked so as to form a sort of fascicle or corymb.

Psychotria, L. — Calyx gamosepalous, 5-toothed; corolla funnel-shaped, 5-cleft; 5 stamens, anthers exserted or included; style bifid; drupe with two seeds, calyx limb attached to the fruit.

P. emetica, Mutis (*Cephaelis emetica*, of Persoon).—Shrubby, erect, oblong-acuminate leaves, ciliated; stipules short, ovate, acuminate; fruit succulent, somewhat globose, of a blue colour. It is found in New Granada, and on the banks of the Magdalena river.

The roots of the plant are perpendicular and knotted, not closely annulated, like the Ipecacuan, and they are distinctly striated. They have a slender axis or meditullium, and a thick friable cortical portion. They yield nine per cent. of emetine. The stem of the plant has a remarkable septate or discoid pith, similar to what occurs in some Euphorbias, as well as in the walnut and jessamine.

Another plant supplies the white or amylaceous Ipecacuan (Poaya do Campo) found in Brazil, New Granada, Peru, and Vera Cruz. It belongs also to *Cinchonaceæ*, the Tribe *Spermacocidæ*, and Genus *Richardsonia*.

Richardsonia, Kunth; *Richardia*, L. — Calyx subglobose, 4-7-partite, corolla funnel-shaped, 3-5-lobed, stamens 3-5, exserted; fruit, 3-4, dry, one-seeded cocci, forming a sort of capsule with the calyx limb on the top.

Richardsonia scabra, St. Hilaire (*R. brasiliensis*, Virey).—Stem with rough hairs; leaves ovate, or ovate-lanceolate, with rough margins; the setæ of the stipules shorter than the sheath; heads many flowered; triangular lobes of calyx ciliated; segments of corolla hairy at the apex. The fracture of the root is not resinous, but farinaceous, of a dull white colour. There is an abundance of starch in the cells. The root contains about six per cent. of emetine. Martius says that it is used as an emetic, in doses of ʒj to ʒij.

In the same section of *Cinchonaceæ* occur species of *Borreria*, which are used like Ipecacuan.

Borreria ferruginea, DC. (*Spermacoce ferruginea*, St. Hilaire); *Borreria Poaya*, DC. (*Spermacoce Poaya*, var. *a*, St. Hilaire).

Another of the emetic roots in Brazil is the produce of a small fine-flowered twiner belonging to the *Cinchonaceæ*, called *Manettia cordifolia*. The genus was named after Xavier Manetti, Professor of Botany in Florence, who published, in 1751, a work on Italian fruit trees.

Manettia, Mut.—Limb of calyx 4-5 lobed, often with secondary ones; corolla funnel-shaped, 4-5 lobed limb; anthers sessile, in throat of corolla; capsule ovate crowned with calyx lobes; peltate seeds.—*M. cordifolia*, Mart. (Bot. Reg., t. 1866). Native of Brazil, banks of the Arroyo de la China, a stream which enters the Uruguay, Entre Rios; hedges in the province of Minas-Geraes, near Villa Rica. Bark of root esteemed in Brazil as a valuable remedy in dysentery; dose, ʒss to ʒjss. It is also used as an emetic.

We now come to another Natural Order, which furnishes plants having the properties of Ipecacuan, viz., the Order *Violaceæ*. Emetic properties are found in the roots of some of the common violets, such as *V. canina* and *V. sylvatica*; but it is especially in the genus *Ionidium* (ἴον a violet, and ἴδιον peculiar) that properties like those of the real Ipecacuan occur.

Ionidium, Vent.—Sepals 5, not prolonged at the base; corolla unequal, 2-lipped, 5 petals, lowest very large with a spur; 5 stamens unequal, 2 anterior with appendiculate anthers; sepals, petals, and stamens remain covering the capsule.

I. Ipecacuanha, Aug. St. Hil. (*Viola Itubu*, Aubl.; *Ionidium Itubu*, H.B.K.; *Pombalia Itubu*, DC.), woods of Brazil, where it is called *Poaya branca* and *Poaya de Praga*. — Leaves alternate, lanceolate-ovate; stipules ovate-lanceolate, acute; lower petals very large; root emetic.

Several other Ionidiums possess emetic properties, as—

Ionidium Poaya, Aug. St. Hil., Minas-Geraes, in Brazil; called Poaya do Campo. *I. microphyllum*, H.B.K., Curichunchulli, 'Companion to the Botanical Magazine,' i. 278. Quito, near foot of Chimborazo; specially used in elephantiasis tuberculata. *I. parviflorum*, Vent., Tr. Mad. Bot. Soc. i. 206. *I. brevicaule*, Mart.; *I. urticæfolium*, Mart. These are all Brazilian species.

The Natural Order *Polygalaceæ* supplies a plant which is called a Poaya or Ipecacuan, viz., *Polygala Poaya*, Spix and Martius. The root is perennial, perpendicular, or slightly oblique, 3-5 inches long, and the size of a writing quill at the top, attenuated downwards and towards the base, divided into spreading branches, twisted in a vermicular manner, contracted at different parts, and marked by cicatrices; the epidermis pale ochre colour, sometimes transversely striated, with a pale spongy cortical portion; at first having a sweetish taste, but afterwards becoming bitter, and a central ligneous white thread, thicker than the bark. On mountain plains of San Paulo and Minas.

One of the *Asclepiadaceæ* yields a kind of Ipecacuan, *Tylophora asthmatica*, W. and A.; (*Cynanchum Ipecacuanha*, Willd.; *Asclepias asthmatica*, Roxb. Fl. Ind.; *Cynanchum vomitorium*, Lam.). It is an East Indian twiner, common in sandy places.

The leaves and roots are an efficacious substitute for Ipecacuan. Dr. Roxburgh used it in dysentery, and Dr. J. Anderson, of Madras, employed it in that disease with great success. It is recommended as a valuable remedy also in asthma, and has been admitted into the Pharmacopœia of India (1869), where the uses are described, pp. 142 and 458. Four other East Indian plants of this Order have been employed for their emetic properties.

Another Order which supplies a plant known as an Ipecacuan is the *Euphorbiaceæ*. In this we meet with *Euphorbia Ipecacuanha*, L., a plant which grows in sandy soils in the middle and northern states of North America. It has an irregular fleshy root, very large in proportion to the plant, running into the sand, sometimes to the depth of six feet. From its stem proceed numerous dichotomous branches on the surface of the ground. The flowers are produced on long peduncles from the forkings of the stem. The root acts as an emetic; it is also cathartic, as might be expected from the character of the Order to which the plant belongs.

OLEATES OF MERCURY AND MORPHIA.

In a Clinical Lecture recently delivered by Professor John Marshall, F.R.S., in the University College Hospital,* he drew attention to the fact that mercurial ointment, which is itself the basis of other mercurial preparations, is merely a mechanical mixture of minute globules of mercury; and said that he had long thought that if a solution of mercury in some oleaginous or unctuous medium could be employed, more immediate and satisfactory results would be obtained from the well-known therapeutical powers of this ancient remedy. In seeking for his object he first dissolved some of the perchloride of mercury in a small quantity of ether, and added to it about four times the amount of oleic acid; but found that this combination freely used on the skin produced much irritation, unless it was employed in too dilute a form to be of service as an absorbent. In Gmelin's Chemistry there is a short account of certain metallic oleates formed by double decomposition; but with this as a guide, he failed to obtain any satisfactory oleate of mercury. Mr. Frank Clowes, to whom he then referred the chemical question, soon discovered that, although the ordinary sublimed scales of red oxide of mercury were with difficulty dissolved in oleic acid, the oxide, precipitated by caustic potash or soda from a solution of the metal in nitric acid (which is a yellow impalpable powder) is, when recently made and well dried, readily soluble in oleic acid, especially when aided by a temperature of about 300° F. At Professor Marshall's request Messrs. Hopkin and Williams have since studied the subject pharmaceutically, and have succeeded in preparing oleate of mercury, and certain solutions of that salt in oleic acid. The strength of the preparations made by them is indicated by the percentage of the oxide of mercury which they contain. The 5 per cent. solution is a perfectly clear pale yellow liquid, resembling olive oil, but thinner; the 10 per cent. solution is also fluid and perfectly clear, but as dark as linseed oil; whilst the 20 per cent. preparation is an opaque yellowish unctuous substance, closely resembling in appearance resin ointment, melting very readily at the temperature of the body, and forming a kind of transparent, viscid, colourless varnish when applied to the skin. The chief care to be observed in the manufacture of these solutions is not to hurry the process, and not to employ a high temperature, or the mercury will be immediately reduced.

Unlike the mercurial ointment so long in vogue, which is a crude, gross, unscientific mixture, very dirty and very wasteful, because so small a proportion of its mechanically admixed mercury is but slowly absorbed, these solutions of oleate of mercury are cleanly and economical in use; and as the diffusibility or penetrating powder of oleic acid is much greater than that of ordinary oils or fats, and as each one-thousandth part of even a minim of these new preparations contains its proper modicum of mercury, they are absorbed by the skin with remarkable facility and manifest their remedial effects with great promptitude. They should not be rubbed in like ordinary liniments or embrocations, but should be *merely applied with a brush, or be spread lightly over the part with one finger*; otherwise they may cause cutaneous irritation, or even produce a few pustules on the skin, especially in certain persons. This result may, however, be obviated by the addition of a small quantity of olive oil, or purified lard, according as an oleaginous or an unctuous preparation is required. Any of these forms may be scented by the addition of essential oils.

In employing these mercurial solutions for combating persistent inflammation of joints, Professor Marshall soon found that the addition of morphia was of very great advantage. For this purpose the simple alkaloid must be used, as neither the hydrochlorate, the acetate, nor the meconate is soluble in oleic acid. For every drachm of the solution of oleate of mercury in oleic acid one grain of morphia may be added. Being, as well as the mercury, completely dissolved, it quite as rapidly penetrates the skin, comes quickly into contact with the extremities of the nerves, and thus, even within a few minutes, acts upon them at their most sensitive points, and speedily produces a soothing effect.

The oleates of mercury and morphia, thus united in one preparation, represent, as it were, a liniment, ointment, or plaster of mercury and opium; but they are far more elegant, economical and efficacious.

* Reported in the *Lancet*, May 25th, 1872.

ELIXIRS AND WINES.*

BY C. LEWIS DIEHL.

At the request of the committee on unofficinal formulæ, I present in the following the formulas used by me for preparing some of the elixirs and wines prescribed by the physicians of Louisville. Many of these have been used by me for several years, as the elixirs of Calisaya, etc., and have been found to be good preparations. Others have only lately been prepared by me, but seem to be desirable preparations, if this class of preparations is at all desirable or necessary. It is not my intention or desire to criticize the propriety of introducing these preparations; but that a necessity exists for formulas which will secure uniformity in their preparation seems to me beyond question. Our markets are flooded with numberless preparations of this kind. Physicians prescribe them, and usually signify the manufacturer whose particular preparation they prefer. As a result of this we are either compelled to keep all of these preparations in stock, or to depend upon the courtesy of our fellow-pharmaceutists when they are prescribed. If we attempt to keep them in stock a considerable outlay of capital is required, with in but isolated instances more than a very meagre chance for a fair return. To depend upon our neighbour for the occasional calls is unfair to him, as it in a measure compels him to carry the stock upon which we may reap profit. But in every way it is unfair to the patient, who is often caused to pay exorbitant prices —even when such price is only a fair advance upon the

* Read before the Louisville College of Pharmacy, January 16th, 1872.

cost—for preparations that, if prepared by the pharmaceutist, would not exceed the cost of ordinary tinctures.

I have attempted to simplify formulas as much as possible, in order that such as are but seldom demanded may be prepared as wanted. With this in view I prepared a simple elixir, an elixir of Calisaya bark, a wine flavoured with orange, various solutions of essential oils in alcohol, and cochineal colouring; of which I usually keep in stock, and prepare by their aid, such preparations as may happen to be in demand.

ELIXIR OF CALISAYA BARK.

Take of Calisaya bark	℥xxiv.
Curaçao orange-peel (ribbons)	℥xvi.
Coriander	℥iv.
Cardamom	℥iss.
Cinnamon (Ceylon)	℥iij.
Anise	℥j.
Cocoa (Baker's)	℥viij.

Reduce to a moderately fine powder; displace with a mixture consisting of one part by measure of stronger alcohol and three parts of water; obtained two and a half gallons of percolate.

Meanwhile prepare from six pints of solution of tersulph. of iron, hydrated sesquioxide of iron by the formula of the Pharmacopœia, measure it, and add to every four measures one measure of alcohol; then add of this sufficient to the percolate obtained as above to deprive it of its cincho-tannic acid. The absence of the latter is readily ascertained by the addition of a drop of muriated tincture of iron to a filtered portion of the liquid in operation, which should not be coloured by such addition. Should colouration result, the intensity or faintness will serve as a guide to the further quantity of hydrate sesquioxide of iron necessary to completely detannate the preparation. As soon as this result is obtained, strain the mixture upon a muslin strainer; and, when the liquid ceases to pass, wash the residue upon the strainer, with sufficient of a mixture of one measure of stronger alcohol to three of water to make the strained liquid measure five gallons. Now triturate together oil of orange (fresh), f℥ss. (or solution, f℥v.; see further on); carbonate of magnesia, ℥vj. When thoroughly mixed, incorporate it with the strained liquid obtained as above, agitate well, and filter through paper; express the filter between muslin, filter the expressed liquid, and mix with the previous filtrate, in which dissolve 15 lb. av. of sugar. If necessary, filter the elixir thus obtained; but simple straining will usually answer.

SIMPLE ELIXIR.

Take Oil of orange (fresh)	f℥j	(or sol. f℥x).
Oil of cinnamon	♏x	,, ♏c.
Oil of anise	♏iv	,, ♏xl.
Oil of bitter almonds	♏ij	,, ♏xx.
Tinct. of cardamom.	f℥x	
Stronger alcohol	℈ij	

Dissolve the oils in the alcohol, add the tincture, and triturate the solution with a previously-powdered mixture of cocoa (Baker's), ℥j.; carb. magnesia, ℥ij. Then add gradually four and a half pints of water, transfer the mixture to a one-gallon bottle, agitate occasionally for several hours, and filter; express the filter between muslin, filter the expressed liquid, mix the previous filtrate, and dissolve in it 3lb. av. of sugar; filter or strain as may be necessary.

The simple elixir thus prepared has the colour of dark Madeira wine, and an exceedingly pleasant taste. It serves as a vehicle for many medicines, disguising them to a great extent and rendering them generally more palatable.

WINE OF ORANGE.

Take Oil of orange (fresh)	♏v (or sol. ♏l.)
Alcohol	f℥ss
Carb. magnes	℥ss

Triturate together, and add syrup, f℥ij.; sherry wine, f℥xiij. ss.; mix thoroughly and filter.

The wine obtained in this way has an agreeable flavour of orange. The use of carbonate of magnesia renders it neutral, and thus enables the introduction of medicinal compounds that are liable to decomposition in the presence of acids.

SOLUTION OF ESSENTIAL OILS.

I have been in the habit of dissolving essential oils that are liable to change in alcohol, and have found these solutions very convenient for measuring minute quantities of oils. They are prepared by dissolving essential oil, one part (by measure), in alcohol fort., nine parts; which strength is invariably meant when, in the formulas, I direct the use of solutions of essential oils.

COCHINEAL COLOUR.

Take of Cochineal	℥j.
Carb. potassa	℥ss.
Powd. alum	℥ss.
Cream of tartar	℥j.
Water	℥viij.

Reduce the cochineal to a fine powder, add the carbonate of potassa, and triturate with three ounces of the water. Allow the mixture to stand one hour, add the alum and cream of tartar successively, and, when effervescence has ceased, the remaining water; filter. This solution imparts to the elixirs a fine red colour; but is in some respects unsatisfactory, as it soon spoils.

The above are all the preparations that need to be kept in stock; and with them, and such other ingredients as are readily obtained by purchase, almost all the elixirs and wines now prescribed may be prepared extemporaneously. The exceptions to these are:—

COMPOUND ELIXIR OF TARAXACUM,

which being used for the purpose of disguising the extreme bitterness of quinia, should be prepared according to the original formula of Mr. Candidus, as communicated by him to the American Pharmaceutical Association.

ELIXIR OF PYROPHOSPHATE OF IRON, QUINIA, AND STRYCHNIA

requires particular manipulation, which precludes the use of simple elixir. The following formula—the result of concert of experiments of my friend Mr. E. Scheffer and myself—has been used by me since autumn, 1869, and I can recommend it as uniformly successful when the manipulation is carefully conducted:—

Take Sulphate of quinia	60 gr.
Strychnia	1 gr.
Citric acid	5 gr.
Stronger alcohol	f℥ij.
Solution of oil of orange	♏l.
Syrup	f℥vj.
Pyrophosphate of iron	℥ss.
Distilled water	f℥vij.
Aqua ammonia	q. s.

Triturate the sulphate of quinia, strychnia and citric acid together until minutely divided, then add the alcohol and solution of oil of orange. Warm the syrup slightly (to about 150° F.), and add to the turbid alcoholic mixture; when, upon stirring, the mixture becomes clear. To this add the pyrophosphate of iron, previously dissolved in the distilled water, and finally aqua ammonia carefully (drop by drop), until the elixir is perfectly neutral to test paper; filter.

The finished preparation has a greenish yellow colour, a pleasant flavour of orange, and is permanent.

ELIXIR OF CALISAYA BARK WITH IRON.

Take of pyrophosphate of iron 128 grains, soften in f℥ij. of water, and stir in gradually 1 pint of Elixir of Calisaya Bark; filter.

ELIXIR OF CALISAYA BARK WITH IRON AND STRYCHNIA.

Dissolve 1 grain of strychnia and 1 grain of citric acid in f ʒij of water, add 1 pint of elixir of Calisaya bark with iron, mix and filter.

ELIXIR OF CALISAYA BARK WITH IRON AND BISMUTH.

Dissolve 128 grains of pyrophosphate of iron and 128 grains of ammonio-citrate of bismuth in 2 fluid ounces of distilled water, add 14 fluid ounces of elixir of Calisaya bark; mix and filter.

ELIXIR OF CALISAYA BARK WITH IRON, BISMUTH AND STRYCHNIA.

Dissolve 1 grain of sulphate of strychnia in f ʒij of water, add 1 pint of elixir of Calisaya bark with iron and bismuth; mix and filter.

ELIXIR OF CALISAYA BARK WITH IRON AND BEEF.

Dissolve ½ an ounce of extract of beef (prepared by Liebig's method) in 1 pint of elixir of Calisaya bark with iron; allow it to stand several days (if possible), and filter.

ELIXIR OF PYROPHOSPHATE OF IRON.

Soften 256 grains of pyrophosphate of iron in ½ fluid ounce of water, add 15½ fluid ounces of simple elixir; mix and filter.

ELIXIR OF BISMUTH.

Dissolve 256 grains of ammonio-citrate of bismuth in 4 fluid ounces of distilled water, mix with twelve fluid ounces of simple elixir, and filter.

ELIXIR OF VALERIANATE OF AMMONIA.

Dissolve 256 grains of valerianate of ammonia in 2 fluid ounces of simple elixir carefully add aqua ammoniæ until the solution is exactly neutralized; then mix with 14 fluid ounces of simple elixir; filter and colour with cochineal colour to a bright red.

ELIXIR OF VALERIANATE OF AMMONIA AND QUINIA.

Triturate 64 grains of valerianate of quinia until minutely divided, then dissolve in it 1 pint of elixir of valerianate of ammonia, and filter.

ELIXIR OF VALERIANATE OF AMMONIA, QUINIA AND STRYCHNIA.

Dissolve 2 grains of strychnia in f ʒij of water, by the aid of just sufficient valerianic acid; mix with 1 pint of elixir of valerianate of ammonia and quinia, and filter.

ELIXIR OF VALERIANATE OF QUINIA.

Triturate 128 grains of the valerianate of quinia until minutely divided, mix with 1 pint of simple elixir, carefully add valerianic acid until the liquid becomes clear, shaking after each addition, and filter.

ELIXIR OF VALERIANATE OF QUINIA AND STRYCHNIA.

Dissolve 2 grains of strychnia, minutely divided, in f ʒij of water by the aid of just sufficient valerianic acid; mix with 1 pint of elixir of valerianate of quinia, and filter.

ELIXIR OF VALERIANATE OF STRYCHNIA.

Dissolve 3 grains of strychnia in f ʒij of water by the aid of just sufficient valerianic acid; mix with 1 pint of simple elixir, and filter.

ELIXIR OF BROMIDE OF POTASSIUM.

Dissolve 1 oz. of bromide of potassium and 1 oz. of sugar in 1 pint of simple elixir; add 20 minims of solution of oil of orange and 10 minims of solution of oil of bitter almonds, and filter. Colour with cochineal colour.

ELIXIR OF BROMIDE OF SODIUM.

Prepare this like elixir of bromide of potassium, substituting bromide of sodium for bromide of potassium, and omitting the colour.

ELIXIR OF BROMIDE OF AMMONIUM.

Prepare this like elixir of bromide of potassium, substituting bromide of ammonium for bromide of potassium, and omitting the colour.

ELIXIR OF HOPS.

Add 2½ fluid ounces of fluid extract of hops—made according to formula for F. E. Gentian, U.S.—to 13½ ounces fluid ounces of simple elixir; mix and filter.

ELIXIR OF LUPULIN.

Triturate 2 ounces of fluid extract of lupulin with 2 ounces of carbonate of magnesia, add 14 fluid ounces of simple elixir; transfer to a bottle, agitate occasionally for several hours, and filter.

ELIXIR OF GENTIAN AND PYROPHOSPHATE OF IRON.

Triturate 100 minims of solution of oil of orange with 2 ounces of sugar; dissolve it in 8 fluid ounces of elixir of pyrophosphate of iron and 6 ounces of simple elixir, add ½ ounce alcohol and ½ a fluid ounce of fluid extract of gentian; mix and filter.

ELIXIR OF CHLORAL HYDRATE.*

Dissolve 2 ounces of chloral hydrate in 1 pint of simple elixir, and filter.

WINE OF IRON.

Dissolve 128 grains of ammonio-citrate of iron in f ʒij of water, add 1 pint of wine of orange; mix and filter.

BITTER WINE OF IRON.

Dissolve 128 grains of soluble citrate of iron and quinia in f ʒij of water, add 1 pint of wine of orange; mix and filter.

WINE OF WILD-CHERRY BARK.

Mix 1 ounce of fluid extract of wild-cherry bark, 2 fluid ounces of syrup of wild-cherry bark, 10 minims of solution of oil of bitter almonds, and 13 fluid ounces of wine of orange. Allow to stand several days, and filter.

WINE OF WILD-CHERRY BARK AND PYROPHOSPHATE OF IRON.

Soften 128 grains of pyrophosphate of iron in f ʒij of water; add one pint of wine of wild-cherry bark mix and filter.

WINE OF BEEF.

Dissolve half an ounce of extract of beef (Liebig's method) in one pint of wine of orange, and filter.

WINE OF BEEF AND IRON.

Dissolve half an ounce of extract of beef (Liebig's method) in one pint of wine of iron, and filter.—*Pharmacist.*

LYCOPERSICUM ESCULENTUM.—TOMATO.

BY THOMAS D. M'ELHENIE.†

My experiments have been directed solely to the isolation of the organic acids contained in the fruit, the examination being undertaken at the suggestion of my preceptor, Mr. T. A. Lancaster, who had in an essay, presented in 1859, demonstrated the presence of tartaric acid, but expressed the opinion that citric acid would be found to exist in it in larger proportion, and probably in sufficient quantity to render it available as a commercial source of the acid. The variety on which I operated was the red tomato, known in the market as the "Tilden"; this is quite solid, of a medium size, and contains comparatively little juice. There are other inferior varieties which contain a larger amount of juice, and have more acidity of taste, and I expect these would be found to contain a larger proportion of acids; but being at the time unable to procure any of them, I was obliged

* This elixir was first prepared by me at the request of a gentleman who habitually used the chloral hydrate, and he finds that the chloral dissolved in this way retains its virtues most completely during the period required for the consumption of one quart. For this reason I have given the formula for its preparation, thinking that if such a preparation is desirable this seems to serve the purpose.

† Extracted from an Inaugural Essay.

to content myself with an examination of the variety named.

I have employed two processes in my examination; the first being mainly that given in the British Pharmacopœia for the preparation of citric acid from lemon juice.

One gallon of juice, freshly expressed from fully ripe tomatoes, was heated to the boiling-point and strained. Keeping it at about 200° F., powdered chalk was added until effervescence ceased. After cooling, the precipitate was separated by straining and filtration, and mixed with two pints of water. To the mixture was gradually added three pints of water, mixed with four fluid ounces of sulphuric acid, some effervescence being produced, probably due to an excess of calcium carbonate. The mixture was boiled gently for half an hour, and filtered. The filtrate, after partial evaporation, was set aside to allow any calcium sulphate which might be present to crystallize. After standing twenty-four hours the liquid was decanted—there being a slight sediment, but no crystals—and evaporated until a slight film began to form on the surface, when it was again set aside.

After standing about three weeks there was a considerable deposit of brown extractive matter, having a crystalline appearance, from numerous small crystals imbedded in it. As this extractive evidently retarded the formation of crystals, and being pressed for time, I continued the evaporation at a gentle heat, until the whole was reduced to the consistence of an extract, which I brought with me on my return to the college, for further examination.

Upon resuming operations in the laboratory of the college, I first made a preliminary examination of a small portion of the mass, according to the method directed in Will's tables, and found present citric, malic and oxalic acids. In order to isolate them, the mass was boiled with a sufficient quantity of water, and the solution filtered. A small quantity of inert matter was left undissolved. The filtrate was neutralized with calcium hydrate, and the precipitate separated by filtration, and reserved.

The filtrate from this was evaporated and boiled until the calcium citrate was precipitated, which was then washed with hot water, on the filter, mixed with a small quantity of pure water, and decomposed by dilute sulphuric acid; the calcium sulphate was allowed to deposit, the liquid was filtered, concentrated and set aside.

After three days a number of crystals were found deposited, but mixed with some viscid colouring matter.

The mother-liquor was decanted, and after concentration was set aside for further crystallization. The first crystals were dissolved in a small quantity of distilled water, the solution filtered, concentrated, and set aside. After standing twenty-four hours no crystals had formed in either liquid. They were then mixed, concentrated and filtered. After standing about two weeks, a small quantity of crystals had formed.

These were separated, and the mother-liquor again concentrated, when a very small product was obtained.

Owing to press of other duties I did not purify the resulting crystals. The yield was, however, very slight, being probably ten grains from one gallon of fresh juice, equal to about nine pounds of fruit.

To obtain the malic acid, the filtrate left after precipitation of calcium citrate by boiling was concentrated, and calcium malate was separated by the addition of alcohol. Allowing it to subside, it was separated by filtration, and the filtrate again treated with alcohol to separate any remaining malate. A small quantity was obtained, and after filtration it was mixed with the first product. This was then dissolved in a small quantity of hot water, the solution filtered, and, after partial evaporation, mixed with an equal bulk of alcohol, and the mixture treated with dilute sulphuric acid.

The resulting calcium sulphate was separated after it had completely subsided, and the filtrate, containing malic acid in dilute alcoholic solution, was partially concentrated. After standing twenty-four hours, no crystals having appeared, it was further concentrated and set aside.

After standing about two weeks, I found it had deposited a quantity of coloured inert matter. It was again partially evaporated and filtered, and in a few days a quantity of crystals were obtained.

While engaged in purifying these with animal charcoal, the entire product was lost by the accidental breaking of the capsule containing the solution, so that I was unable to ascertain the exact weight of the purified product. It was, however, larger than that of citric acid.

To obtain the oxalic acid, the precipitate obtained by neutralizing the original solution with calcium hydrate was treated with hydrochloric acid, the solution diluted, filtered, and neutralized by ammonia, when calcium oxalate was precipitated.

This was boiled with a solution of potassium carbonate for two hours, and filtered to separate calcium carbonate. The filtrate was then mixed with alcohol to just below the point of precipitation, and the mixture treated with dilute sulphuric acid. The potassium sulphate being insoluble in alcohol, readily subsided, leaving oxalic acid in alcoholic solution.

This was then partially evaporated and set aside. After standing several days, a deposit of colouring and extractive matter was formed. This was separated, and the solution further concentrated and treated with animal charcoal.

After a few days I obtained a quantity of small crystals. These were dissolved in a small quantity of distilled water, and again treated with animal charcoal and recrystallized. The yield was about equal to that of malic acid.

The second process was as follows: One gallon of fresh juice was boiled down to the measure of two pints. This was set aside and occasionally observed. After it had been standing about two weeks I found no result except the formation of a considerable brown deposit of extractive. It was then mixed thoroughly, and evaporated at a gentle heat to about three fluid ounces.

This was then operated on in essentially the same manner as the first, diluting the liquid, filtering and neutralizing with calcium hydrate, and then isolating the acids from their lime salts.

The results were similar, the yield of malic acid being rather larger. It has been stated tartaric acid existed in tomatoes in small quantities. I failed to obtain it, but hope at some future time to continue an investigation of various small acid fruits, and repeat that of tomatoes with better facilities. I infer from the results obtained that the acids exist uncombined in the fruit.

It is evident, however, that tomatoes are not available as a source of either of the acids.—*Amer. Journ. Pharm.*

NEW DESCRIPTION OF VALVE FOR GLASS TUBES.

Messrs. Kay Brothers, of Stockport, have invented a simple and effective contrivance which they propose to adapt to infants' feeding-bottles for the purpose of preventing the return into the bottle of food after it has once been drawn into the suction tube. In these bottles the suction tube consists, as may be seen in the woodcut, of a piece of ordinary glass tubing, contracted at the bottom to fit the rounded end of a small piece of glass, which freely passes up and down and acts as a valve. When suction is applied this valve is raised as far as the indentation in the tube, thus permitting the free ingress of the food to the tube; upon the removal of the suction it falls, and blocking up the orifice, prevents the return of the food, and therefore the necessity of exhausting the air afresh

SOOTHING SYRUP.

THE value of quietness is variously estimated by the persons immediately and individually concerned. There is, however, much less difference of opinion as to the advantages of soothing the disturbers of our peace, in whatever character they appear, and procuring quietness at their expense and without inconvenience to ourselves. But here, again, there are many forms of persuasists, and some persuaders approach so nearly to the limit of coercion that legal objections are taken to their use; and hard labour, in lieu of rest, is the penalty which dogs the heels of those who favour their employment.

The value of quietness is very well known to baby-farmers, and with them it is reduced to a market price, and has its regular quotation. In Mr. ERNEST HART's evidence before the Infant Life Protection Committee of the House of Commons, he gave the customary quotations, ascertained in the course of his inquiry into the subject of baby-farming, which has led to the introduction into the House of Commons of the Bill now in progress. It varied, if we remember rightly, from a penny to twopence a day, according, we presume, to the pretensions of the baby-farmer or the squallings of the baby. A deduction according to this tariff was found to be commonly made where the mother supplies the "quietness" with the baby; the extra payment is demanded when the baby-farmer is expected to purvey food and quietness.

Translated from pastoral into pharmaceutical language, quietness means drugging by opiates; and to baby-farmers who live to save appearances, and to mothers who prefer to indulge in the luxury of fine sentiments, together with an easy and vicarious performance of maternal duties, the reading of a plain-spoken article recently published by Dr. W. F. M'NUTT, of San Francisco, will produce much distress. "Mrs. WINSLOW's Soothing Syrup—a poison." Pharmacists are well aware of the fact that this and most, if not quite all, the soothing syrups, cordials and elixirs sold for the especial benefit of infants, under the most amiable titles, conceal opium, which is unquestionably a deadly poison, and one which needs the utmost care and skilled vigilance to rob it of its danger when infants are compelled to swallow it. According to an analysis which this physician quotes as reliable (*American Journal of Pharmacy*, May 1st, 1871), ten drachms of Mrs. WINSLOW's Soothing Syrup were found to contain "nearly one grain of morphia, and other opium alkaloids, to the ounce of syrup." The specimen of soothing syrup analysed was made by CURTIS and PERKINS, of New York, who are the only manufacturers. According to Dr. TAYLOR, GODFREY's cordial was found by Dr. PARIS to contain half a grain to an ounce. A case has been reported where half a tea-spoonful of GODFREY's Cordial which equalled one thirty-second part of a grain of opium, was found to have caused the death of an infant; in one year twelve children were reported to have been killed by this mixture alone. DALBY's carminative contains, according to Dr. PARIS, one-eighth of a grain of opium to an ounce; one tea-spoonful, therefore, contains one sixty-fourth part of a grain of opium; but, says TAYLOR, "like most of these preparations it varies very much in strength." An infant is reported to have been poisoned by forty drops of this nostrum; thus it will be noted that the whole tribe of infantile soothers belong to the tribe of poisons. Of none, however, has so terrible an account ever been given as that given by Dr. M'NUTT of this American invention. The directions quoted are "for a child of six months old and upwards, one tea-spoonful three or four times a day, until free from pain." A tea-spoonful of this compound, according to the quoted analysis, contains little less than twenty drops of laudanum. Three drops is as much as a prudent physician would venture to give; and if such directions be widely disseminated and generally carried out, it is only surprising that we do not hear yet more frequently of inquests upon narcotized infants.

Certainly the Inspectors under the Infant Life Protection Bill should direct their attention to this subject, and it is one to which pharmaceutists can not be indifferent. We do not know to what extent our English children may be soothed by this particular agent, but Dr. MURRAY of San Francisco, states—"I have ascertained that there are about one hundred thousand two-ounce bottles of it sold annually in this city, containing about one hundred and eighty thousand grains of morphia which are given annually to the babies of this State."

From this datum it is calculated that 14,000,000 grains of morphia are annually administered to the babies of the United States. The objections to passing a prohibitory law against narcotic nostrums for children are not so strong as the objections to a Maine liquor law for adults, for infants cannot be supposed to have as yet either a natural or an acquired craving for stimulants, and their free will is rather impaired than improved by compulsory drugging.

Admitting, however, the existence of considerable difficulties in the way of any compulsory legislation of this kind, it is obviously improper that the most dangerous preparations of opium should be sold for administration to the most sensitive subjects without adequate, clear, and invariable notice to their responsible guardians as to the character and dose of the potent drug which they are administering. Every coroner will, we believe, concur in the opinion that the blind and ignorant use of opiates is a fearfully fertile cause of infantile mortality; the testimony of poor-law medical officers, clergymen and pharmacists is to the same effect. The dangers of such a system are increased by veiling them, and those who persist in applying this coercive "quieting" to their infants should not be allowed to shelter themselves under the plea of ignorance, of delusion, or misdirection. In this, we believe, all pharmacists will concur. The process of "angel-making" will find no abettors in our ranks, and pharmacists will be among the first to forbid this massacre of the innocents. If we are to have woman suffrage, the female legislators might with advantage occupy themselves with this subject at their earliest convenience.

BRITISH PHARMACEUTICAL CONFERENCE.

The Town Council of Brighton has generously placed one of the best rooms in the Pavilion at the disposal of the Conference for the Annual Meeting of August 13th and 14th.

To make any very great improvement in the excellent Feeding Bottles that are now offered to the public by several manufacturers would appear to be a difficult task, and there is little doubt that, in the main, that article will retain its present form for many years. But a simple contrivance that has been introduced by Messrs. Kay Brothers, of Stockport, for the purpose of preventing the return of the food from the tube into the bottle when suction is removed, has the merit of ingenuity and of accomplishing the object desired.

While upon this topic we may remark that where india-rubber fittings are used, they should always be made of pure unvulcanized black tubing, since it is to the sulphur used in the process of vulcanization that the generation of sulphuretted hydrogen sometimes complained of is due.

Dr. Mackintosh, of Downham Market, states in the *Lancet*, that a groom having, while cleaning the surgery, helped himself to a quantity of sulphate of zinc, under the belief that it was Epsom salts, let his imitative faculty have play by prescribing and administering an ounce of it to—himself. Violent vomiting and severe purging soon followed, and painful cramps and other uncomfortable symptoms were felt during the next day; but on the third day he was able to walk, and has since quite recovered,—a result that his master attributes to the greater part of the sulphate having been thrown off by the vomiting, and the remainder by the purging.

EXAMINATIONS IN LONDON.

May 22nd and 24th, 1872.

Present—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Haselden, Ince, Linford and Southall.

PRELIMINARY.

The undermentioned Certificates were received in lieu of this examination.

Certificate of the Law Society of the United Kingdom.

Evans, Robert Lloyd ...... Birmingham.

Certificates of the College of Preceptors.

Crook, Charles W. W. .... Plymouth.
Allen, Charles Bowen .... Penzance.

Certificates of the University of Oxford.

Atkins, William Ralph...... Salisbury.
Hubard, Alfred Edward .... Birmingham

Certificate of the University of Cambridge.

Simon, Henry James...... Burgh-le-Marsh.

MAJOR.

Five candidates were examined; of these *three* failed. The following *two* passed, and were declared duly qualified to be registered as Pharmaceutical Chemists:—

*Kendall, Edward Basnipp.. Nottingham.
Laugher, William .... West Bromwich.

MINOR.

Forty-nine candidates were examined; of these, *twenty-five* failed. The following *twenty-four* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

*Walden, Robert Woolley...... Newark.
Dismorr, Henry.............. London.
Evans, Gwilym .... Swansea.
Elliman, Samuel Francis ...... London.
Adams, Frederick Joseph...... Gravesend.
Appleton, Arthur James ...... Attercliffe.
Equal { Turner, Joseph Kitchin ...... Whitehaven.
Equal { Verity, William .... Northampton.
Corder, Sheppard Ransome .... Norwich.
Greaves, Abraham Walter .... Chesterfield.
Crisp, Frederick Arthur ...... Clapham.
Nicholls, Arthur Lindley .... Shanklin.
Brown, George Matthew...... Landport.
Savell, Edward Pearce ...... Southampton.
Simcock, George .... Birmingham.
Stewart, Edward Hinton .... Tiverton.
Russell, Matthew Rawlings .. Whitehaven.
Savery, William Henry ...... Burslem.
Tansley, Arthur James ...... Cheadle.
Francis, William Henry ...... Diss.
Walton, William Henry ...... Croydon.
Allison, Reuben.............. Glantwrch.
Eckersley, Moses .... Wigan.
Partridge, Samuel, jun. ...... Dudley.

The above names are arranged in order of merit.

* Passed with honours.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

A lecture upon "Coal Gas" was delivered at the rooms of the above Society, by Mr. P. H. Mason, on Wednesday, May 22nd.

The Chairman (Mr. Thompson), in opening the meeting, said he had just been informed that Mr. Sutton could not be present, and that Mr. Mason at the last moment had kindly consented to take his place. Much as he regretted the absence of Mr. Sutton, he felt sure Mr. Mason would not only instruct but amuse them.

The Lecturer began by describing the process employed in the manufacture of gas; and after briefly noticing the by-products, gave a very explicit account of the constituents of good gas, and the more frequent impurities. He also explained the causes that led to variations in the quality of gas, and showed some experiments illustrating the methods used to obviate these variations, and to increase the illuminating power. Finally, he demonstrated the methods for estimating the impurities and illuminating power.

The lecture was fully illustrated by experiments, which evoked repeated applause.

The Chairman, in a humorous speech, moved a vote of thanks to Mr. Mason, which was seconded by Mr. Martin. The meeting concluded with a vote of thanks to the Chairman.

On Sleep.

BY PROFESSOR HUMPHRY, F.R.S.

The Professor first gave a brief account of some of the changes that take place in the tissues when their function is active, and explained that during this time a slight deterioration of structure takes place, which affecting the voluntary system—the muscles and the hemispheres of the brain—causes the sense of tiring, and necessitates a period of rest for the restoration of the tissue to its former condition. In the case of the muscles this rest is provided for by periods, quickly alternating periods, of action and cessation of action. But in the case of the brain, the actions upon which consciousness, volition, etc., depend, cannot be thus frequently suspended. Their continuance is needed for the safety of the body during long periods, through the whole day for instance; and longer periods are therefore required for repair. These are the periods of sleep.

He next took a cursory glance at the different parts of the nervous system, explaining that the upper regions of the brain are those which minister to consciousness and volition, the intellectual operations, etc. He showed that the functions of these regions not only can long be suspended without interfering with the action of the lower parts of the brain which are more immediately necessary to life, but that they are very easily suspended, slight causes, such as a jar or a shock, or an alteration in the blood current, being sufficient to stop the action of these parts, and deprive the person of consciousness. The spontaneous stoppage of their action, consequent on the slight deterioration of their structure from the continuance of their functions during the day, is the proximate cause of sleep during the night; and the periodic recurrence of sleep is in accordance with the periodicity observed in several of the nutritive functions, and indeed witnessed in many of the other operations of nature.

After observations upon the condition of the brain during sleep, the circumstances that conduce to sleep, the time that should be allotted to it, and other points, the Professor entered at some length into the subject of dreams. These he regarded not, as has been supposed by some, to be a necessary attendant on, or feature of, sleep, but rather to be the result of an abnormal condition. In the natural state we should pass from wakefulness to complete unconsciousness, and *vice versâ*, quickly, almost instantaneously; and many persons habitually do so. But the transition period is sometimes prolonged, and stages are observable. The first thing that occurs is the lowering or cessation of that control over the mental processes which is the highest of our powers, the one requiring the greatest effort and the one most easily lost. In this condition the thoughts ramble unchecked, chase one another confusedly over the mental field, and give rise to all sorts of incongruities of the imagination. At the same time being unrestrained, they are excited, and evince efforts of memory and even of combination which in the regulated state of wakefulness they are quite incapable of. In this way the images of persons and places, of events and items of knowledge long forgotten in the ordinary state, are recalled with distinctness; and we fancy that new information has been acquired, when it is only forgotten facts that are recalled. He did not agree with the physiologists who conceive that dreaming depends upon an inequality in the condition of different parts of the brain, some being excited or wakeful, while others are quiescent or asleep. He rather took the view that all the parts of the cerebral hemispheres combine in each of the efforts of control, consciousness, memory and other mental acts, that all suffer alike from these effects, alike need the restoring changes which take place in sleep, and together *pari passu*, pass through the stages on the way to and from sleep in which dreaming, sleep-walking, etc., occur.

SOCIETY OF ARTS.

April 24, 1872.

Nuts, their Produce and Uses.

BY P. L. SIMMONDS.

Continued from page 960.

The nutmeg may, perhaps, be included under the edible nuts, as it is an important article of commerce In the four years ending with 1841 the average import was only 121,000 lb. In 1850 it had risen to 312,418 lb., and now the import and consumption is 538,000 lb., worth 1*s.* 6*d.* per pound.

Formerly the production was a monopoly of the Dutch East India Company; and although the cultivation has been attempted in other quarters, it only succeeds in the Straits Settlements and the Islands of the Eastern Archipelago. In the Banda Islands the produce is about 530,000 lb. annually (in 1847 it was as much as 755,000 lb.), and all above that quantity used to be rigorously destroyed. The collected nuts when ripe are dried in the sun or by the heat of a moderate fire till the shells split. They are then sorted and sometimes dipped in lime-water, to preserve them from the attacks of insects.

The shape of the nutmeg varies considerably, being spherical, oblong, and egg-shaped; but the nearer they approach sphericity of figure, the more highly are they prized. Those of good quality should be nearly round, heavy, weighing on an average ¼ of an ounce.

The broken nuts are made to yield, by expression or boiling, a concrete oil, termed nutmeg-paste or butter, which is used for flavouring. Its specific gravity is about ·948. What is erroneously termed oil of mace is obtained by distillation from the nutmeg, and should bear its name.

The long (wild or male) nutmegs of commerce are the produce of *Myristica tomentosa*, and are not so much esteemed as the round.

The cashew-nut (*Anacardium occidentale*) is another tropical fruit, occasionally imported for its sweet kernels, and which has this peculiarity, that the nut is attached to the fruit, instead of growing within, as is usually the case. A thick, black, oily, viscous juice, called cardole, is obtained in the East Indies from the pericarp, which is a powerful vesicating agent. The white kernel, which is oleaginous and of an agreeable flavour, furnishes an oil considered superior to olive oil.

From North America small quantities of two edible nuts, the peccan and the hickory, are occasionally imported. The former is the seed of *Carya olivæformis*, the latter of *Carya alba*. An excellent oil for burning and machinery has been made from the hickory-nut, in

Ohio, which continues in a fluid state at a very low temperature. It is used for delicate machinery, and when properly refined would be suitable for watchmakers. The pig-nut, *C. glabra*, is preferred in the manufacture, on account of its thin shell and greater yield of oil, which is bitter. The oil obtained from the ordinary shell-bark, and large sweet hickory-nut, might come into general use for the table.

The sapucaya-nut is a pleasant edible nut, which comes in small quantities from South America. The fruit in the capsule is suspended from the branches, and presents an appearance like small cocoanuts. The monkeys are exceedingly fond of the nuts.

The "cabombas," or cups of the Zabucai or monkey-pot (*Lecythis urnigera*, Mart.), which contain the sapucaya-nuts of commerce, are frequently of great size and excessive hardness, and are closed by a lid like that of a pyx or soap-box. The aborigines of parts of South America use these not only as goblets, but as pots and dishes. Hence Linnæus called the plant *Lecythis ollaria*. The lid of the cup falls off when ripe. Portuguese turners make pretty boxes and other fancy articles out of these solid cups. In the Brazilian Court, at the London Exhibition of 1862, some handsomely-carved and mounted specimens were shown.

The butter-nut, or Souari nut, is the fruit of *Caryocar tomentosa*, of South America. Only very small quantities are received. It yields an edible oil. The fruit of another species, *Caryocar brasiliensis*, furnishes, in Brazil, the Piquia concrete oil, of a brown colour, retaining much of the flavour of the fruit.

In China and Japan, under the name of gingko nuts, the seeds of *Salisburia adiantifolia* are eaten.

Before passing from this section of edible nuts, I may draw attention to the various fancy uses in the series kindly shown by Messrs. Fortnum and Mason, which includes pistachio nuts and pistachio chocolates, glacé walnuts and marron glacés, green candied almonds, burnt almonds, sugared almonds, and sugared nuts. And in contrast with these finished products of the confectionery trade, we have the almond and cocoanut rock of the sweet shops, for children, which sell under the curious names of stick-jaw and eggs and bacon.

Oil Nuts.

I pass on now to a consideration of the oil-yielding nuts. I might properly speak of the olive as the principal one, which would as equally of right come into the category as some other oil-bearing seeds and fruits I shall have to allude to, but then, as it is never spoken of commercially as a nut, I must pass it over.

After the olive, the palm family furnish the principal quantities of oil to commerce, in those two important and well-known oils, palm oil and cocoa-nut oil. From the fruit and kernels of the oil palm of Western Africa (*Elais guineensis*) we now draw our largest supply of vegetable oil. In the year 1808, 200 tons of palm oil were received from Africa; in 1827 the quantity had increased to 4700 tons. Some few years later it had risen to 14,000 tons. What do we find it now? Last year (1871) 51,087 tons, valued at £1,789,000, were imported. Palm oil has become one of the most important articles of commerce from the west coast of Africa, especially to this country, although we are not the only importers. The collection and shipment has done more than anything else to suppress the slave trade. The oil, as manufactured for home consumption in Africa, is slightly different from that prepared for export. It is darker coloured, and is obtained by beating, pressing, and boiling the fruit (sarcocarp). Palm-nut oil is obtained from the seed or kernel by roasting, beating, and boiling. Formerly these kernels were thrown away; now they form an important trade. In 1863, the palm kernel trade, then newly introduced, furnished for shipment at Lagos 2665 tons of oil; in 1869, 20,394 tons were exported from that port, besides one and a half million gallons of palm oil.

The next great source of oil from the palm is that obtained from the pulp of the cocoa-nut; and considering the wide-spread range of this palm, it is strange that the import of the oil has made such little progress compared with its great rival, the African oil palm. One reason may possibly be that the fruit is more generally used for food, and for the refreshing drink in the nuts when young. The cocoa-nut palm is cultivated in great abundance on the Malabar and Coromandel coasts, Ceylon, the Laccadives, and everywhere in the Straits Settlements and the islands of the Eastern Archipelago.

In the West Indies, Central America, and Brazil, the cocoa-nut is extensively grown; there are groves of it for about 280 miles along the coast of Brazil, from the river St. Francisco to the bar of Mamarguasse. From Pará alone 7½ million cocoa-nuts, worth £130,000, are annually shipped to the United States and elsewhere.

The cocoa-nut is very widelyspread over the Pacific Islands. From the Fiji Islands 500 to 600 tons of oil and 1500 cwt. of cocoa-nut fibre are annually shipped. The trees there, however, suffered severely a few years ago from a violent hurricane, from which they have hardly yet recovered.

Many years ago Dr. Royle estimated the average produce of cocoa-nuts from the whole of Malabar at from three hundred to four hundred millions annually, valued at £500,000, and copperah, or the dried kernels, was exported for as much more. Thirty years ago there were in Travancore more than 5½ million cocoa-nut trees, and since that period the cultivation has largely increased, as the demand for the oil and the coir has advanced. From Cochin more than 3000 tons of the latter are exported.

I have not alluded to cocoa-nuts under edible nuts, although the 3½ millions imported here doubtless go to the fruiterers' shops and hucksters. They are brought principally from the West Indian Islands, British Guiana, and Honduras, and range in price from 12*s*. 6*d*. to 17*s*. 6*d*. per 100. Some small quantity of dried copperah is also imported, for the oil-presser's use. The husk forms an important article of commerce, and is readily bought by the brushmakers, being even more valuable than the nut. The quantity of nuts imported would yield about 530,000 lb. of coir.

The products of the cocoa-nut are numerous; besides the oil, fibre, yarn, rope, and matting, brushes and brooms are made of the coir from the husk; spoons, ladles, drinking-cups, and carved fancy articles from the shell.

So far back as 1857 the value of the products of the cocoa-nut, shipped from Ceylon, was £274,462, viz.:—

		Value. £
Cocoa-nuts. . . .	1,420,856 No. ..	3,717
Coir rope	18,881 cwt. ..	13,984
Coir yarn. . . .	31,652 ,, ..	21,364
Copperah or dried cocoa-nut pulp	20,381 ,, ..	12,143
Oil	1,767,431 gals. ..	223,254

These were chiefly the produce of native plantations, situated on the south-west side of the island.

There were about 22,000 acres of cocoa-nut trees under cultivation by Europeans, which were being annually added to, but none of them were then fully in bearing.

In the ten years ending with 1869 the value of the shipments from Ceylon were—

Oil.	£1,445,928
Coir	349,622
	1,795,550

The quantity of oil shipped does not vary much, being on the average 1½ million gallons yearly; but the coir has doubled in the last ten years, now amounting to

67,000 cwt., worth about £45,000, for the mere husk of the cocoa-nut.

A cocoa-nut tree, growing in a favourable soil in Ceylon, may produce from 80 to 100 nuts annually, having from eight to 12 branches, or spadices, each bearing five to 15 nuts. It continues to bear for 60 or 70 years. The pericarp of 40 nuts gives about 6lb. of coir. In some parts of Ceylon the natives separate the coir by burying the husks along the borders of the extensive salt-water lakes, whence, after a few months, they are dug out very clean, the fibres easily separating from the cellular tissue of the husk. This mode of preparing the fibre prevents the offensive smell emanating from macerating the husk in water.

The following is an analysis of the cocoa-nut:—

Water	39·7
Albumen	0·5
Emulsin	1·1
Oil	29·3
Amygdalin	14·0
Sugar	3·6
Woody fibre	9·5
Gum	1·2
Mineral matter	0·2
	100·0

Or, in other words, the proportions in one pound of the kernel are:—

	oz.	grs.
Water	6	14
Albumen		35
Emulsin		77
Oil	4	303
Amygdalin	2	106
Sugar		252
Woody fibre	1	228
Gum		147
Mineral matter		14

The oil is ordinarily procured by first extracting the kernel from its outer integument or shell, and boiling it in water. It is then pounded, and subjected to strong pressure. After boiling over a slow fire, the oil floats on the surface. This is skimmed off as it rises, and again boiled by itself, Fourteen or fifteen nuts will yield about two quarts of oil. A somewhat different practice obtains on the Malabar Coast. The kernel is divided into half pieces, which are laid on shelves, and underneath a charcoal fire is kept in order to dry them. After two or three days they are placed on mats, and laid in the sun to dry, after which they are put in the oil press. When the oil is well extracted by this method, a hundred nuts will yield about two and a half gallons of oil. This is the method usually resorted to when the oil is required for exportation, the former when merely used for culinary purposes.

Of late years the application of steam power or hydraulic pressure for the purpose of procuring the oil has been attended with the greatest advantage in Ceylon. It is requisite that care should be taken not to apply too great and sudden a pressure at once, but by degrees an increasing force, so as not to choke the conducting channels of the oil in the press. The oil becomes solid at about 70°. It is curious that when cocoa-nut oil is first manufactured there is no unpleasant smell for the first 30 or 40 hours, but after that it acquires that rancid taste and peculiar odour which no scent will entirely kill. Fresh expressed cocoa-nut oil is used by the Malay women in the Eastern Archipelago in the hair. It is perfumed by allowing the flowers of the jasmine, the tuberose, and other plants to remain for some time in it, the fat oil of the nut extracting and retaining the essential oil of the fragrant flowers. Cochin oil bears a higher price than that of Ceylon. Poonac, or the refuse oil-cake, is sold as food for poultry and for manure.

The trade in cocoa-nut oil is steadily increasing at the Seychelles; fresh plantations are being laid out, and others coming into bearing. The quantity shipped in 1869 was 127,112 gallons, valued locally at about £16,000. From Penang there is an export trade in oil and copperah. Cocoa-nuts are grown in small quantities throughout the Straits Settlements, but it is only here and there that plantations of any magnitude are met with.

Coir is the fibrous rind of the nuts, with which the latter are thickly covered. There are several ways of stripping the fibre from the husk. One is by placing a stake or iron spike in the ground, and by striking the nut on the point the fibre is easily stripped. The fibre is greatly improved in quality and appearance by beating, washing and soaking. The tannin which this subject contains prevents the fibre from rotting. The fibre is rather difficult to twist, but coir-yarn is made into good ropes, and forms the strongest, lightest and most elastic cables for ships.

The fibrous husk of the cocoa-nut is not its least valuable product, and gives rise to a very large trade both in the East and to Europe. At first it was much used in this country for stuffing mattresses and cushions, but its applications have been enlarged and its value greatly increased by mechanical processes; and in a small pamphlet issued by Mr. Treloar twenty years ago, he stated that its natural capabilities having been brought out, coir has been found suited for the production of a variety of articles of great utility and elegance of workmanship, table mats, fancy baskets and bonnets. Instead of being formed into rough cordage only, and mats fabricated by hand, by means of ingeniously constructed machinery, the fibre is rendered sufficiently fine for the loom, and matting of different textures with coloured figures is produced, while a combination of wool in pleasing designs gives the richness and effect of hearthrugs and carpeting. Brushes and brooms for household and stable purposes; netting for sheepfolds, pheasantries, and poultry-yards, church cushions and hassocks; hammocks, clothes lines, cordage of all sizes, and string for nurserymen and others; for tying up trees and other garden purposes; nose bags for horses; mats and bags for seed crushers, oil pressers, and candle manufacturers, are only a few of the varied purposes to which the fibrous coating of the cocoa-nut is now applied. The cocoa-nut shell furnishes cups which, carved on and set in silver, are a great ornament. It also makes small baskets, cups, ladles, spoons, and other such domestic articles, and fanciful ornaments. By being burned and pulverized and prepared with other ingredients, it produces blacking not inferior to Day and Martin's, lamp black, black-paint, etc.

The fruit of the Chili palm (*Cocus chilensis*) is, in every respect like the cocoa-nut, except that it is not larger than a walnut, about an inch in diameter. Every tree produces a great number, which are highly esteemed, and they form a considerable article of export to Peru. A curious method is employed to free the nut from the green husk in which it is enveloped, a process that was formerly attended with a very great loss of time and labour. A number of cows and oxen are driven into an enclosure, where a quantity of the fruit is spread, and being fond of its husk they immediately begin to feed on the fruit, only slightly masticating it in the first instance, and swallowing the whole. Afterwards, while chewing the cud, the nuts are rejected, and when the meal is finished, a heap of them is found before each of the animals, perfectly free from the husk, and thus the cattle are supplied with food at a season when little grass remains on the hills.

Before leaving cocoa-nuts, I must not omit mention of the sea cocoa-nut of the Indian Ocean, the produce of *Lodoicea Seychellarum*.

The fruit, from floating in the sea, was known long before the plant which produces it, or the locality in which it was found, and various fables were invented as to its origin, and marvellous virtues attributed to it.

The few known specimens which existed were valued at an enormous price till, in 1745, the discovery of the Seychelles Archipelago made known the habitat and nature of this singular production. Three of the islands composing the archipelago—Praslin, Cunense, and Ile Ronde—were covered with magnificent forests of this unique palm, and their soil strewed with its huge and singularly shaped nuts. The value of their shells as domestic utensils for various purposes was at once perceived, and from that time to the present they have supplied to the inhabitants the place of baskets, bowls, jars, dishes, measures for grain and liquids, drinking vessels, paint-pots, etc. The trees are fast being destroyed. On Ile Ronde not a plant remains. Cunense has a considerable number of fine young trees. At Praslin a great many have been destroyed by fire, and there are not, perhaps, a score of trees in the other islands. This palm is of very slow growth, for the trunk does not show itself till twenty or twenty-five years after the germination of the seed, and then it takes fourteen or fifteen years before it blossoms.*

I have no recent statistics of the trade in these nuts; but in 1859, 3,310 of these were exported, valued at £831, and 11,800 lobes or cups made of them, valued at £590. Although they have now lost much of their traditional repute, they are still held in such estimation by the negroes and poor people of other islands, that sailors always try to bring away some in their vessels. When preserved whole, and perforated in one or two places, the shell serves to carry water, and two of them are suspended from opposite ends of a stick. Some of these nuts hold six or eight pints. If divided in two between the lobes, each portion serves, according to its size and shape, for plates and dishes, or drinking-cups, these being valued, like calabashes, for their strength and durability.

A fixed oil (called Manteiga de Assahay) is extracted by decoction from the fruit of the *Euterpe oleracea* palm, which abounds in Pará. The oil is of a greenish colour, slightly bitter, and used for lighting and other purposes.

The pulp of the fruit of the Aoura palm, of Guiana (*Astrocaryum vulgare*), yields an oil which is used for many different purposes. A yellowish, bitter oil, used for soap-making in Brazil, is obtained by decoction and expression from the fruit of *Sagus taedigera*, which is abundant in Pará.

From the nuts of *Œnocarpus bacaba*, a palm also abundant in Brazil, an oil of a clear green colour is obtained, which, when purified, is used for lighting and culinary purposes. From the fruit of other species—*O. pataua* and *O. disticha*—fluid oils, clear, yellow, and transparent, are obtained, which, when purified, are inodorous, and used in cooking in place of olive oil.

There are two or three species of *Carapa*, the nuts of which yield a fixed oil. Crab oil of Guiana is from the *Carapa guianensis*. It is extremely bitter, but used externally for the hair and for soap-making. It is abundant in Pará, where it is known as andiroba oil. The nuts are so common in some of the districts of French Guiana that, when they are ripe, the soil is covered at least a foot deep with them for many hundreds of yards. That of Africa, known as mote grease, from mote or kundoo nuts, is from the *Carapa talicoonah* or *touloucouna*, which yields 33 per cent. It yields 70 per cent. of oil.

I have here a pomade alleged to be made with this oil, and said to be used by the East Indians for beautifying, softening, and increasing the growth of their hair, and which, according to the label, has wonderful properties; but it is to be regretted that intelligent pharmaceutical chemists should not have known, after figuring and labelling the plant with its scientific name, that Guiana is not in the East Indies, and that the oil is not likely to be carried and used there when an allied indigenous species, *Xylocarpus granatum*, is to be met with.

(*To be continued.*)

Parliamentary and Law Proceedings.

THE SHIPPING OF BENZINE.

The following letter in reference to the report of a case heard at the Thames Police Court, which we last week quoted from the *Daily News*, has been addressed to that journal by Messrs. Curling, of St. Mary Axe:—"In your impression of Wednesday, in the report of the proceedings against our firm, for shipping a case of benzine without notifying its contents, it is stated in error that the case shipped and containing benzine had been described on the outside as 'Patent Medicine.' We beg to state that the goods were not shipped for our account, that the words 'Patent Medicine' were not written on the case, and that the consignee's mark and number 'P. H. and Co., 721,' were the only marks upon it. The omission of the word benzine, complained of by the dock company, arose from accident only. But the alleged false representation of the contents of the case as being 'Patent Medicine' (given in the report) obliges us to request a correction of the latter statement, as it is calculated to injure us, and is without the slightest foundation."

Reviews.

THE STUDENT'S POCKET COMPANION TO THE BRITISH AND LONDON PHARMACOPŒIAS OF 1851 and 1867, comprising the Formulæ of both Pharmacopœias in Parallel Lines, an Abbreviated Materia Medica, Tables, etc., with a Medico-Botanical Map. By GEORGE BARBER, Pharmaceutical Chemist. Sixth Edition. London: Philip and Son, and Simpkin, Marshall and Co. 1872.

The usual result when a "pocket companion" has arrived at the dignity of a sixth edition is that it ceases to be adapted to any other pocket than that of an "Ulster" great coat, or of a prestidigitateur. So many temptations to improvement, so many additions that might be useful, present themselves, and it is so necessary to keep abreast of the time with new information, that the compiler requires to exercise considerable discrimination in culling the choicest only, or his work will soon belie its original name One proof at least of the fitness of the compiler of the work now lying before us is to be found in the fact that, while it contains far more matter, it would really take less room in the pocket than the third edition. This is due to the ingenuity with which every part of the book is made use of, even to the apoplectic-looking title-page.

One feature of this little volume is that in almost every section the subjects are arranged in what might be termed a "graphic" manner. The arrangement of the P. L. and P. B. formulæ in parallel columns, which enables the mind more readily to compare differences and to associate them together, is characteristic of the plan of tabulating information which is acted on throughout.

Some of the sections that appear for the first time in this edition will prove very useful and interesting. On the inside of the cover at the commencement of the book is one of Mr. Bellow's ingeniously contrived concentric calculators* for the conversion of grams into grains, and at the end is one for the conversion of litres into fluid ounces, drachms and minims. There is also a "pharmaceutical or medico-botanical map of the world," in which the names of the articles of the materia medica yielded by a district are set down after the fashion of the names of towns in ordinary maps. As far as it goes, this picturesque way of teaching materia medica, although not new, is interesting; and it is curious to notice how in a few spots—Central America and the West Indies, India and the Eastern Archipelago—the names cluster unusually thick. There are one or two points, however, that, without being hypercritical, might be objected to.

* See PHARM. JOURN., 3rd ser. Vol. I. p. 396.

For instance, although the last edition of 'Pereira' tells us that "the source of Brazilian isinglass is unknown," it does not help us much to see the name "Isinglass," set down in an inland district of Brazil, about equidistant from the Atlantic and Pacific Oceans, and far from any river marked in the map. Tapioca, too, is rather vaguely placed—almost alone—in the centre of Africa, certainly a part from which at present a very small quantity is received. The synopsis of the chemical reactions which take place in the preparation of the acids, salts, etc., and a synopsis of the elements and salts of the British Pharmacopœia, present that information in a compact form, and a scale having on one side the Fahrenheit degrees, and on the other the Centigrade degrees, together with a scale of four inches side by side with one of ten centimetres, give a clearer idea of the relations of the several systems than can so easily be obtained in any other way. The sections under the titles "American Eclectic Remedies," "Granulated Preparations," "Suppositories," etc., are very suggestive of an origin in another well-known "Companion;" this, however, may perhaps be accepted by the author of that work as a compliment.

In closing our notice of this little book we would suggest that, although the larger part of the work appears to be stereotyped, to cancel a page now and then would be preferable to the adoption of the clumsy expedient of reproducing the errors of former editions and adding a slip of errata. The book, however, is so well suited to the purpose for which it is issued, that there is little risk in predicting that its compiler will have many opportunities of remedying any slight defect it may contain.

The Chemical Note Book for the Use of Students. London: S. Deacon, King Street, Borough. 1872.

To those chemical students who regularly take notes while at work—and no methodical study of chemistry can be carried on in any other way—this book will be very useful. It consists of a series of blank forms, in which the student can enter a description of the substance upon which he is experimenting; and of the deportment of its solution with such reagents as hydrochloric acid, sulphuretted hydrogen, ammonic sulphide, ammonic carbonate, sodic phosphate, etc.; record additional experiments for the detection of metallic or non-metallic constituents; and finally, supposing his search to be successful, the name of the substance and confirmatory experiments. The forms are bound in a stiff cover, and sold at a very moderate price.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 3. ......*London Institution*, at 4 p.m.—"Elementary Botany." By Professor Bentley.

Tuesday, June 4. ......*Royal Institution*, at 3 p.m.—"Development of Belief and Custom." By Mr. E. B. Tylor.

Wednesday ...*Royal Microscopical Society*, at 8 p.m.

Thursday, June 6. ......*Royal Institution*, at 3 p.m.—"Heat and Light." By Dr. Tyndall.
Chemical Society, at 8 p.m.
Linnean Society, at 8 p.m.

Friday ....*Royal Institution*, at 9 p.m.

Saturday, June 8. ......*Royal Institution*, at 3 p.m.—"Chemical Action of Light." By Professor Roscoe.
Royal Botanic Society, at 3·45 p.m.

The following journals have been received:—The 'British Medical Journal,' May 25; the 'Medical Times and Gazette,' May 25; the 'Lancet,' May 25; the 'Medical Press and Circular, May 28; 'Nature,' May 25; the 'Chemical News,' May 25; 'English Mechanic,' May 24; 'Gardeners' Chronicle,' May 25; the 'Grocer,' May 25; the 'Journal of the Society of Arts,' May 25; 'Grocery News,' May 25; 'Moniteur Scientifique-Quesneville' for May; the 'Canadian Pharmaceutical Journal' for May; the 'Leavenworth Journal of Pharmacy' for May.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[315].—MOUSTACHE POMADE.—Will any correspondent kindly favour me with a recipe for a pomade or paste that will change the colour of a very light or grey moustache to a dark brown, or a mouse colour, without staining the skin or injuring the hair.—Delta.

---

[316].—REMOVAL OF STAINS.—I shall be obliged if some reader will kindly give me a form of preparation for removing pyrogallic acid and nitrate of silver stains from the skin without injuring it.—A. R.

ADULTERATION OF PEPPERMINT OIL.—It is stated by Mr. E. B. Shuttleworth, in the *Canadian Pharmaceutical Journal* (vol. v. p. 272), that large quantities of American oil of peppermint had been imported into Canada which, upon examination, was found to be adulterated with castor oil and alcohol. The writer having submitted 55 lb. to distillation, obtained an oily distillate which, when separated, consisted of 18 lb. of oil of peppermint of good quality; the residue in the still (21 lb.) was found to be castor oil, and the difference between the sum of these two weights and the original quantity represented the amount of alcohol present. A mixture of these constituents in the above proportions yielded a clear and presentable oil, strongly resembling the genuine article. Its density was slightly lower (·894 at 60° F.), its reactions with iodine were precisely similar, and it dissolved perfectly in rectified spirit. The presence of the fixed oil may, however, be detected by the characteristic stain it leaves upon paper, and that of the alcohol by agitation with an equal volume of water, when a milky emulsion will be produced.

PREPARATION OF KOUMISS.—The following instructions for the preparation of Koumiss have been sent to the *British Medical Journal* by Dr. Townsend, of Cork, who says that Koumiss so prepared was used by his father, many years since, in the treatment of phthisis, and answered well:—

"Take one quart of new milk, one noggin of good thick milk or fresh butter-milk, and three or four lumps of white sugar. Mix all together from jug to jug till the sugar is quite dissolved. Put it in a warm place to stand for ten hours. It will then be quite thick. Pour it again from jug to jug till it is smooth. Bottle it in soda-water bottles; let it remain in a warm place for thirty-six hours (twenty-four in summer). Use the best velvet corks; tie them down; shake the bottle well for five or six minutes before it is opened. It will have whey at the bottom when fit for use. It is to be made every day, and taken in quantities. Its fermentation is the test of its excellence."

ETHER GLUE.—An excellent liquid glue is made by dissolving glue in nitric ether. The ether will only dissolve a certain amount of glue, consequently, the solution cannot be made too thick. The glue thus made is about the consistency of molasses, and is doubly as tenacious as that made with hot water. If a few bits of india-rubber, cut into scraps the size of buckshot, be added, and the solution be allowed to stand a few days, being stirred frequently, it will be all the better, and will resist the dampness twice as well as glue made with water.—*Scientific American*.

CLAUSE 16 OF THE PHARMACY ACT.

Sir,—At the Annual Meeting last week, I drew attention to the 16th clause of the Pharmacy Act, which says that it shall be lawful for any executor, administrator or trustee, to carry on business for the benefit of a widow, by means *only* of a duly qualified assistant, and I stated that I knew of several instances of injury and hardship arising out of the effect of this clause. I gave a case in point:—A widow was left sole executrix, and the property and business devised to her absolutely. She administered, took possession in her own undoubted right, and then her troubles began—"Her name was not on the register;" a "brother in trade" took note of this, informed our excellent secretary, and he, bound hand and foot by Clause 16, sent her notice under pains and penalties that "she must qualify or sell" within a given time. She was nearly fifty years of age, her children all daughters, and passing even the Minor was in her case impossible. I went with her and a friend to the Society, met with a kind official reception, and came away with the assurance that she had no right to carry on the business in her husband's name, while her own name had no legal status; she therefore sold for £800 that which had brought in a clear profit of £460 a year, thus losing at least £400 a year, and started life again by attempting to keep a school, which will be a long time before it keeps her. She is, however, well-fitted for her compulsory work; and if any of my brethren wish a child well cared for, I shall be happy to forward her name and address.

We all make mistakes, and a mistake has been made in passing this clause; can nothing be done to remedy it? And would it not be well for every husband and father in making his will, to see to it, that he understands Clause 16 of the Pharmacy Act of 1868?

Praying you to grant me space for this communication, I am, etc.,

WM. FRED. SMITH.

London, 280, *Walworth Road*,
May 22*nd*, 1872.

[*** Mr. Smith appears to overlook the fact that the widow to whom he alludes was carrying on the business of Chemist and Druggist *on her own account*, and that she could not therefore claim the special exemptions provided in the Pharmacy Act, 1868. The 16th section of the Act, which creates the exceptions, must be strictly construed in favour of the public, so that the widow of a deceased chemist and druggist would not stand in any more favoured position than any descendant, ancestor, or collateral relative of a deceased chemist and druggist; in short, no relative of a chemist and druggist can claim any special exemption in right of relationship, and *the only persons who can claim the special exemptions are those who stand in positions of trust as defined by the Statute.*—ED. PHARM. JOURN.]

PHARMACEUTICAL EDUCATION.

Sir,—At a time when there is so much difficulty about pharmaceutical education, it is, I think, the duty of all connected with our business to aid the important consideration with such practical suggestions as may occur to their minds. On reading the discussion on this subject at the Annual Meeting, and observing the uncertainty in which the matter remains, it occurs to my mind that the best plan would be to concentrate the completion of the pharmaceutical education at Bloomsbury Square, and to make some such arrangement as the following:—Require that every apprentice should spend the last four or five months of his indenture at the Society's rooms, and be boarded and lodged in two or more houses under the control of a superintendent, and be required to attend the necessary courses of lectures, and afterwards undergo the necessary Minor and Major examinations, so as to qualify him for going into business or taking a responsible situation, the whole matter, including board, lodging, and instruction, to be limited to a sum not exceeding £25. There should be, I think, two sessions of four or five months' duration during the year; and assuming there would be, say 150 at each, the sum at disposal for this purpose would amount to £3750 to each session, or £7500 per annum.

JOS. TAPLIN.

13, *Corn Street, Bristol*,
May 26*th*, 1872.

Sir,—Your Report of the Annual Meeting will have been read throughout the country with a feeling of gratification that the cause of provincial education has come so prominently forward. The subject was so thoroughly discussed that it may seem impertinent to add another word; but I should like to raise one voice in urgent support of Mr. Schacht's (or the Government) plan of "aid for results," as being the most just in principle and the most extensive in application.

The existence of provincial associations is an encouraging feature; and if the choice lay between aiding them and confining pecuniary advantages to "the square," little could be said against their receiving the requested help. It is policy not to lose for want of asking, and not to ask too late. But if the principle is to be "each association for itself," the usual benison is likely to fall upon the "hindmost"; and if progress is to move on this line, it must be two generations before we of the country, pure and very simple, can hope for any benefit. We, "rurals," compared with our brethren of the metropolis and of the large towns, must always be in the position of country mechanics who, with their rude implements, have to compete with their *confrères* of the city who have the help of every modern invention. Schools of chemistry!—classes for the study of botany!—associations for education! They are the pleasures of Tantalus. Education is a mount that we must climb alone, uncheered by the voices of our fellows. We carry, very much "'mid snow and ice, the banner with that strange device." We are asking little when, having climbed, we desire "aid for results"—aid to be given in proportion to the means at the disposal of the Council, and hence to the detriment of none. The large towns, with their larger advantages, would get the larger share; to them that have would be given; but the solitary chemist in the country would put in his claim on achieved success, and feel that he had a share in the commonwealth, for the scheme is calculated to call forth the latent talent of the country.

I am greatly pleased to find that Mr. Schacht has been returned to the Council so near the top of the poll. I trust that he will so powerfully advocate his own plan that it will be adopted by the executive, and thus secure—what it should be the aim of all executives to attain—the highest good of the greatest number.

HENRY H. POLLARD.

Ryde, May 27*th*, 1872.

CHEMISTS' CLUB.

Sir,—Some twelve months ago, I believe the subject of a 'Chemists' Club" was suggested in your columns; at the time, I must say I thought but little of it, but having since had to come to town to attend the Laboratory previous to the Society's examinations, I have much felt the want of such an institution, and have heard many remark how glad they would be of a "Club," or some place of resort where they could have the comforts of home combined with moderate charges.

If any (and I am sure there must be several) amongst your numerous subscribers have felt this want and would like to see it supplied, I should be very pleased if they would communicate their ideas in your next number.

ONE WHO WOULD GLADLY BE A MEMBER.

May 14*th*, 1872.

WOMEN AND PHARMACEUTICAL EXAMINATIONS.

Sir,—Are women admitted to the examinations of the Pharmaceutical Society, or were the founders of the opinion of Cornelius,

"I do not like her . . . I know her spirit,
And will not trust one of her malice with
A drug of such damn'd nature"?

INTERROGATIVE.

[*** According to Mr. J. Stuart Mill's definition of the word "person," a woman may present herself for examination.—ED. PHARM. JOURN.]

The Microscope in Pharmacy.

Sir,—With reference to Mr. Pocklington's article on the "Microscope in Pharmacy," in which he mentions his recent discovery of the fact that ground-nut cake is used as an adulterant in coffee, cocoa, etc., I beg to say that this sophistication was first detected and fully exposed by me in the 'Food Journal' of March last, a matter of priority which I think was entitled to some notice at his hands.

I may mention that, out of the hundreds of samples which have come under my observation as analyst to the above journal, I have never found this starch in anything but two samples of cocoa, which, although bought at different shops, emanated, I believe, from the same manufacturers. Its flavour when roasted would prevent its being used for coffee to any extent, and I am sure the sample of butter referred to by Mr. Pocklington as containing both *Arachis hypogea* and *brains* is an exceedingly exceptional case; good mutton and beef fat being much more easily obtainable and better suited in every way to the views of the butter makers than either of these rare adulterants.

John Muter, Ph.D., F.C.S.

231, *Kennington Road, S.E.*,
18th May, 1872.

*** For the satisfaction of Dr. Muter the above letter has been submitted to the author of the article in question, who has forwarded to us the following reply:—

"I have much pleasure in admitting Dr. Muter's claim to priority in exposing the use of *Arachis hypogea* in adultera tion of cocoa, etc. My omission to ascribe "honour to whom honour is due" may be explained by the fact that I had not read the article in 'Food Journal,' to which Dr. Muter alludes, at the time I wrote the article in which I refer to the use of *Arachis*. As Dr. Muter is aware, independent discoveries and rediscoveries are not only possible but exceedingly probable in work of this description, where we have to deal with facts of tolerably easy observation.—H. P."

Chemists and Druggists' Entrance Fees.

Sir,—I was glad to notice that Mr. Vizer brought the above subject before the Annual Meeting. I have always held that it was very impolitic on the part of the Council to demand them, and unjust to the body of chemists and druggists. We are told, however, that as outsiders we have done nothing for the benefit of the Society, and therefore it is only right and fair we should pay a fee for the privilege of becoming a member. My object in writing this letter is to inquire what is the privilege in connection with the Society that calls for two guineas? It can't be the Journal; that I read regularly and can borrow at any time. Perhaps some of your readers that have paid the fees can enlighten my understanding on this point, because I am quite willing to become a member and should have joined two or three years ago but for this fee barring the entrance. And whatever privileges belong to membership, I have always held—right or wrong—that a chemist and druggist on the other hand confers a benefit on the Society upon becoming a member. Mr. Vizer clearly proves this in his remarks, and I trust the entrance fees will be swept away altogether. R. B.

Halifax.

*** We trust some of our readers will respond to this inquiry, and in deference to our correspondent's desire that they should do so we abstain at present from saying anything more than to suggest that the question of *cui bono* should not be considered merely in regard to direct individual advantage.—[Ed. Ph. Journ.]

Sir,—Love of fair play impels us to address a few words to you in reference to a suggestion advanced at the Annual General Meeting, viz., to raise the Minor examination fee to eight guineas.

We should like to know of the gentlemen who so zealously desire to "clap it on" to the already sufficiently embarrassing impediments between the poor assistants and the inevitable examinations,—are our supervisors prepared for their part to "clap on" a compensating increase on the salaries they offer; or do they expect to raise the status—or rather compel the assistants to raise for themselves their degree of qualification, "including analysis, toxicology, and so forth," and yet continue to offer such scandalous salaries as appear unblushingly in the advertisement columns of the Journal; for instance, £20 to £25 (in the number for May 4th). It is no refutation of this to say that there are some, and there are we know, honourable exceptions. "Too many want the pudding without paying for it," as Mr. Humpage said.

We speak feelingly on behalf of those who will have to encounter what we have passed through; and perhaps it was the same cause produced the contrary effect on the gentleman who advocates that severity on the "Minors" that will no longer affect him, and the abolition of members' subscriptions that perhaps would affect him, more agreeably.

Anyhow we fail to see the logic of his arguments. The humble "Minor," with his notoriously pitiful "screw," is to be mulcted of nearly treble the present fee, whilst "those alone who have the extra abilities (?) and ambition"—the Majors, who mostly go in for the title with the view of using it in business on their own account—their "honorary title" is to be made "more valuable and appreciated" by abolishing fees; or making them life members for five guineas!

Now in our humble judgment, if any alteration is needed to encourage the ambitious and at the same time deter the incompetent, some such plan as this would be far more equitable and efficacious.

Let the successful (and therefore presumably deserving) candidates have returned to them the greater portion of their fees, say two-thirds, while as to the too ambitious and unprepared ones, who give the examiners most trouble, let them lose more than at present, say proportionate to their deficiency as shown by their marks. On this simple principle might be adjusted a sliding scale of reward for merit, and at the same time a salutary detergent to warn off "those who are not so fully qualified as they should be." Not to take up more space that may be better occupied, we remain,

J. P. C.
J. S.
A. J. T. } A Minor Triumvirate.

24, *Methley Street, S.W.*

Pharmaceutical Curiosities.

Sir,—I live a very few miles from London, just on the borders of Buckinghamshire, and have been often struck with the "peculiar" knowledge that is required to supply the wants and requests of the "chaw-bacon" population about here.

I have had applications for "sollofolossity" (I write it as pronounced), and because I at first hesitated, and failed to catch the meaning of the strange sound, I was looked upon as profoundly ignorant of the first principles of "yokel" materia medica.

I have been asked for "karplumb," of which to this day I remain in hopeless ignorance; "blood markery," "gum cotcheter," "skivender leaves." By way of helping me, I asked what the latter were for, and was informed for "lapputs of the jints." Not being sufficiently informed with regard to "lapputs," I was unable to supply my customer, but dare say he got "skivender leaves" lower down or higher up, for there are a great many "shining lights" in our street.

I had a somewhat obscure prescription from one of our rural physicians the other day, and will enclose it for your perusal. I question if you or our respected London examiners could translate it, so have written our interpretation underneath.

2 p of blodsom peaive. (2*d.* balsam of capivi.)
2 p of grans of blood. (2*d.* of dragon's blood.)
2 p of rotan apal. (2*d.* bitter apple. Written above rotten apple.)
2 p of sweet niter. (2*d.* sweet nitre.)

I could write a very curious dictionary of synonyms, but you have had a full dose now, and it is the kind of stuff to be administered only *pro re natâ;* but if agreeable you may have the dose repeated at a moderate interval.

Uxbridge, March 26th, 1872. Flint.

Sir,—Thinking that some of my brethren in the trade may feel somewhat interested and amused at the strange compounds in use by our ancestors, I send an extract from an old pharmacopœia of 1693, entitled *Pharmacopœia Bateana.* The contrast of the two P. B.'s (past and present) is rather striking. The following is a formula for preparing Vinum Ecphracticum; a wine opening obstructions:—

R. Live Earthworms, having a red Circle on their Necks No. 24, bruise them in a Marble Mortar with Currants cleansed ℥iv., adding Rhenish Wine lb iij., Crystal Mineral (dissolved in the Wine) ℥ss, strain and make it very limpid and pure by often passing it through Hippocrates his sleeves. Dose ℥iij thrice a day with Aqua Cinnamomi hordeata ℥j. It is a noble Diuretick.

Vinum Viperinum.

R. Live Female Vipers, gathered in the Spring time, No. vj. digest them (the vessel being stopt) without heat for six months, in lbvj. best Spanish wine or Canary, then strain out for use. It is a most celebrated thing against the Leper Grecorum or Leprosie, the Elephantiasia, Barreness, Plague, &c., and prolongs Life. Dose ℥iij. or ℥iv. twice a day for some considerable time.

Syrupus Limacum. Syrup of Snails.

R. Garden Snails gathered before the Rising of the Sun, freed from their shells and cut in pieces lbj. Sugar Candy in fine powder lbss., mix them and put them into Hippocrates his Sleeve in a Cellar, that the Liquor may drop through in a syrup. Dose j. spoonful every hour, in Ulcers of the Lungs, Consumptions, &c.

Spiritus Sanguinis.

Distil it from the Blood of a sound young Man, putrefied in Sand, and then rectifie it, S. A.

I might go on multiplying formulæ equally quaint and nasty, but hesitate to encroach on your space.

C. S. Miller.

Newport, Isle of Wight,
April 18th, 1872.

Pharmaceutical Mnemonics.

Sir,—That 50 per cent. of those who enroll for the Minor examinations are frequently "plucked" can by no means encourage the numerous candidates; however, each has his fling, and trusts that the gods will be propitious and the examiners not too severe. Sometimes the greatest "muff" succeeds, and the intelligent mind who could hardly endure the drudgery of cramming the Pharmacopœia receives a remittance of two guineas, with a polite intimation that he may resume his studies for another three months. One reason that so many fail is that, being obliged to devote so much time in committing to memory the compositions and proportions of the multitudinous preparations of the Pharmacopœia, little time remains for the far more important and interesting studies of chemistry and botany. But since the examiners are inexorable, and their laws, like those of the Medes and Persians, unalterable, cannot something be done to lighten our load? Since no man cares to remember two hours after he has passed his examination the composition of charta epispastica, or the infinity of preparations into which cinnamon, ginger, and camphor may enter,—could not the "sublime crammer" Stokes come to our assistance?

Many mnemonical systems have been tried, but the majority have failed from their impracticability, and their ponderous machinery. Perhaps one of the simplest methods of committing to memory is by association, and the occasional use of doggerel rhymes. Who could forget that œgle marmelos belonged to the Natural Order Aurantiaceæ, if he would only associate Marme*los* and Marma*lade*? What schoolboy does not remember the exceptions to the general rule of nouns of the second declension ending in *us*, from the fact that,

"Alvus, humus, vannus, colus,
 Though belonging to the second,
Are feminine; and virus (juice),
 With pelagus, are neuter reckoned;
Vulgus mostly goes with these,
But may be masculine if you please"?

When the ingredients to a preparation are numerous, it may be useful to compose a distich, as for,

Emplastrum Calefaciens,
 Resin, Wax, Soap, Plaster, and Nutmeg Oil,
 Resin, Plaster, and Flies (the water must boil).

Or three lines may be required as for Mistura Ferri Aromatica:

Let the bark, cloves, calumba and finest iron wire,
With mint water stand till three days expire,
Tinctures, orange, and Cardamoms then ye'll require;

or the hexameter verse may sometimes serve as for Emplastrum Cantharidis,

Cantharidis, resin, and wax, and then there's suet and lard.

It may be occasionally necessary to find some strange resemblance betwixt words; imagine an examiner showing you some Pareira root, and asking you what it was, what would be your immediate reply? "*Cissampelos Pareira.*" Resembling, "This sample is Pareira." Or sometimes things may be easily remembered from the fact that they are not what their names would indicate. I have never failed to recognize the root of the Veratrum viride, the moment I remarked that though viride may mean green, this root has a decidedly yellow tinge; and I can easily remember that though bis may mean twice, bismuth has not bivalent but trivalent quantivalence. When you wish to remember the atomic weight of iron, think of an iron 56 lb. weight falling on your toes. That the egg which is ordered in the Pharmacopœia in the preparation of the Mistura Spiritus Vini Gallici, is obtained from the Gallus Banckiva will never be forgotten if you will picture to yourself a French cock crowing on a bank; or that the *Sambucus nigra* belongs to the Natural Order Caprifoliaceæ, the moment one imagines a goat eating elder leaves in a country lane.

The fertile genius of the pharmaceutical student will furnish him with a thousand mnemonical tricks if he will only habituate himself; and the more ridiculous the similarity which may exist betwixt the two ideas, the more easily will they be remembered.

Let us hope that some day a little less drudgery and more science will be required of us, in the meantime we will humbly bend to the yoke of our venerable and worthy examiners and *cram*. S. F. E.

Tinct. Ferri Perchloridi.

Sir,—I have just observed, in p. 806 of the Journal, Mr. Wilson's suggestion respecting Tinct. Ferri Perchlor., and incline to query whether a still better plan would not be to use equal parts of Sp. Vini. Rect. and Aq. Dest. for diluting the strong solution. This makes it keep well, and for retailing at any rate the use of weaker spirit need hardly be objected to.

April 16th, 1872. J. F. T.

Messrs. Curling and Co.—Your communication to the 'Daily News' did not appear until after last week's number of this Journal had gone to press.

W. G. Taplin.—We are unable to understand your question. We know of no such class as that to which you appear to refer.

"*Dyson.*"—(1.) Mix the essential oils with the olive oil and shake with an equal bulk of water; then pour in the alkalies gradually, shaking after each addition; next add the remainder of the water, and lastly the tinct. cantharid. (2.) The work mentioned is a very good one.

G.—An answer to your question will be given in a future number.

M. P. S.—We are not able to give any reply to your question, which is one that falls within the province of a medical man.

"*Lux.*"—We think the label you propose would require a stamp, but recommend you to consult the Excise authorities at Somerset House.

J. Davidson. — (1.) Ranunculaceæ. (2.) Leguminosæ. (3.) Aurantiaceæ.

"*Pharmacist.*"—They could be ordered through Messrs. Williams and Norgate, Henrietta Street, Messrs. Trübner, Paternoster Row, or any respectable foreign bookseller.

J. Hindle.—There is no limitation as to age.

"*Cecil.*"—(1.) You will find formulæ for Liq. Quinæ Ammon. on pp. 675 and 737 of the first volume of the present series. (2.) Bentley's 'Manual,' Oliver's 'Elementary Botany,' or Cooke's 'Structural Botany.' (3.) The usual subscription for the current year.

P. Z.—Chi'rāta.

Communications, Letters, etc., have been received from Mr. H. Long, Mr. Rimmington, Mr. R. Procter, "Delta" "Shade of Cocker," T. B.

THE ECONOMIC AND MEDICINAL VALUE OF THE GENUS RHUS.

BY JOHN R. JACKSON, A.L.S., MUSEUM, KEW.

Some attention has recently been directed in Natal towards the cultivation of various species of *Rhus* yielding sumac as a prospect of establishing a new industry in the colony. As an article for the dyers' and tanners' use, sumac ranks very high. In North America the berries as well as the bark of *Rhus glabra* are extensively used by the country people in the preparation of a brilliant black dye. The berries are likewise used in medicine as a refrigerant and febrifuge. In Porcher's 'Resources of the Southern Fields and Forests,' we read, on the authority of Dr. Fahnestock, that an infusion of the inner bark of the root is employed as a gargle, and is considered almost as a specific in the sore throat attending mercurial salivation. An infusion of the leaves, sweetened with honey, is serviceable, applied in the same way, and for cleansing the mouth in putrid fevers. From another North American species (*R. copallina*, L.) a wash is made, which is used in the cure of ringworm. The berries are acid, and a cooling drink is made from them. The leaves are said to be used for adulterating tobacco. Several other species of *Rhus* grow in North America, some of which are introduced plants, but are valued on account of their chemical properties. The most interesting, however, are the extremely poisonous species, *R. venenata*, Dec., and *R. toxicodendron*, L. The accounts which have at different times been given of poisoning by these plants almost equal those of the upas. The following, however, as given by Dr. Bromfield, may be relied upon:—"The Rev. Dr. Bachman, of Charleston, being once on a botanical excursion with some friends in the neighbourhood of that city, they came upon a specimen of the poison ash (*Rhus venenata*, Dec.), and felt desirous of gathering specimens for examination. This they proceeded to do, though warned of the consequences likely to accrue from handling it. The doctor stood aloof from a danger which he knew to be inevitable in his own person on near approach or contact. The result was, some of the party suffered severely; the inflammatory action reaching up the arms to the trunk in one, in another only as high as the elbows, whilst in a third the effects were confined to the hands, which, as is usual in these cases, became swollen, inflamed and finally ulcerated. The rest mostly escaped the poison. On his return home, Dr. B. found a branch of the shrub in his vasculum, which had been put there by some sceptical joker amongst certain of the party, who affected disbelief in the poisonous properties of the plant. This he requested his daughter, who was not susceptible of the poison, to take out of the box and destroy; but, at her suggestion, permitted it to be dried for his herbarium. The next day symptoms of poisoning came on; intumescence of the entire body and lower extremities, attended with intolerable pain and irritation, confined him to bed for several days; nor was it till after many weeks that he was able to resume his duties. For several years after he was subject to a periodical recurrence of the erysipelatous inflammation which marks this particular poison." Other instances of poisoning by this plant have also been recorded; one in which some persons were seriously affected by the fumes arising from the wood while burning, the other in which a swarm of bees was poisoned simply by alighting on one of the trees.

Though none of the species of *Rhus* find a place amongst medicinal plants in use in this country,—except, perhaps, as homœopathic medicines,—several of them are so used in the States of America. The most important species, in a commercial point of view, are *R. coriaria*, L., and *R. cotinus*, L. Both of these are natives of Southern Europe, and furnish the well-known article known as sumac, which is the broken and powdered leaves and twigs, and is much used in tanning light-coloured leathers.

In South Africa several species of *Rhus* are known. At the Cape the bark and twigs of *R. tomentosa*, L., and *R. lucida*, L., are used for tanning purposes; and it is with the idea of increasing the value of the indigenous plants of the colony, as well as furthering the introduction of others, that the subject of sumac cultivation has engaged the attention of the colonists of Natal.

SULPHOVINATE OF SODA: ITS PREPARATION AND PURGATIVE PROPERTIES.

BY M. LIMOUSIN, PHARMACIEN.*

In the year 1870, the purgative properties and the advantages presented by the sulphovinate of soda over the other saline purgatives usually employed in therapeutics were pointed out by Dr. Rabuteau, in a memoir communicated to the Academy of Medicine. At the request of Dr. Blache, who desired to verify the assertions made in this communication, the author undertook to prepare some of the salt; and on the 21st of July in the same year he presented to the Academy of Medicine a specimen obtained by following pretty nearly the process indicated in most works on chemistry. This sulphovinate was very pure and well crystallized, but its high price (45 to 50 fr. the kilogram) was a serious obstacle to its introduction into therapeutics.

After several attempts, M. Limousin succeeded in obtaining the salt by a much more economical process, the description of which is the object of the present paper:—A kilogram of pure sulphuric acid, sp. gr. 1·715, and a kilogram of concentrated alcohol, about 96°, are introduced by means of two funnels (one for the alcohol and the other for the acid) into a third funnel arranged in a flask plunged into a freezing mixture or kept in a current of cold water, the flow of the two liquids into the flask being so regulated as to keep the alcohol in excess. The mixture is kept for four or five days at a temperature of 20° C. to 25° C., then diluted with five or six litres of distilled water, and saturated with about 1500 grams of pure carbonate of baryta diluted with a sufficiency of distilled water. When the point of saturation is attained, the liquid is left to deposit the sulphate of baryta, and afterwards filtered. The solution of sulphovinate of baryta so obtained is saturated by 850 to 900 grams of pure carbonate of soda dissolved in four litres of distilled water. When no more precipitate is formed by the addition of the alkaline solution, and the liquid is neutral to test

* Abstracted from a paper read before the Société de Pharmacie de Paris, March 6, 1872 (Journ. de Pharm. et de Chimie [4], vol. xv. p. 271).

paper, the transformation of the sulphovinate of baryta into sulphovinate of soda is complete. The liquor, decanted and filtered, is evaporated in a water bath to about sp. gr. 1·33, and left to crystallize. The crystals, after draining, are dried in a stove. The salt so obtained is of great purity, and may be kept without alteration. With the quantities above indicated, about one kilogram of the product is obtained. If the salt be free from sulphate of soda and sulphovinate of baryta, chloride of barium and sulphuric acid will not give a precipitate in a solution in distilled water.

Contrary to what has been said as to the instability of the sulphovinate of soda, M. Limousin has found that, when well crystallized and well dried, it may remain exposed to the air without decomposing, absorbing moisture, or efflorescing. A solution was kept for more than a year without decomposing into sulphate of soda and alcohol, which result, however, follows if it be heated to 120° C. or 130° C. It is necessary to use pure carbonate of baryta, since the native carbonate (witherite), besides containing impurities, is much less readily acted on by the sulphovinic acid; the carbonate, however, regenerated by the decomposition of the sulphovinate of baryta, may be preserved for future operations. The employment of carbonate of lime to saturate the liquid gives a bad result, as it is impossible afterwards to clear the solution from the lime, which prevents the crystallization.

The author finds that by this process one part of acid is sufficient for the transformation of one part of alcohol into sulphovinic acid, instead of the two parts usually indicated in chemical works; the use of half the baryta that would be necessary to saturate the excess of acid if two parts were used is thus saved. It is, however, very important to use a pure spirit, as when prepared with badly rectified alcohol, the salt has a disagreeable odour that cannot be got rid off.

The formula for sulphovinate or ethyl sulphate of soda is $C_4H_5O, NaO, S_2O_6 + 2HO$, or $(C_2H_5)NaSO_4 + H_2O$. It crystallizes in hexagonal tables, containing 10 per cent. of water of crystallization. It is freely soluble in water, dilute alcohol and glycerine; slightly soluble in absolute alcohol, and insoluble in ether. Its solubility is much greater than sulphate of soda, water at 18° C. dissolving only about 17 per cent. of the latter salt, but about its own weight of the sulphovinate. This difference might be utilized in saturating directly the mixture of sulphuric acid and alcohol with carbonate of soda, and obtaining the two salts in successive crystallizations.

A solution of sulphovinate of soda undergoes a lowering of temperature (13° C.) nearly double that of sulphate of soda (7·5° C.). Heated in a capsule over a lamp flame, the salt swells, and at about 180° C. disengages the alcohol it contains, which may be ignited; when, if the alcohol used has been well rectified, the bisulphate of soda remaining will be white; if not, it will be more or less coloured.

The sulphovinate of soda has the cool taste peculiar to all the salts of soda; it is nearly free from bitterness, and has a sweet after-taste that makes it more easily tolerated than the sulphate, while as a laxative it appears to be about three times more powerful than that salt, and much more prompt. It is given at the "Charité" to adults in 20 to 25 gram doses, and by Dr. Blache to children in 10 to 15 gram doses, sweetened with syrup. Among the advantages claimed for it over other saline purgatives are, that its administration is not followed by constipation, and that there is not the danger of the formation of vesical calculi that sometimes attends the use of salts of magnesia.

Sulphovinate of soda may be administered alone, dissolved in *eau sucrée*, or in a draught sweetened with a flavoured syrup, or in solution in water charged with carbonic acid. This last forms a beverage much more agreeable in taste than the citrate of magnesia, and has the advantage of not undergoing alteration for a long time.

SUPPLIES OF OPIUM AND SCAMMONY FROM TURKEY.

BY P. L. SIMMONDS.

It may prove interesting to the trade generally to have some reliable figures as to the two important drugs which we draw from the Ottoman Empire. In Turkish opium there has not been any important fluctuation of late, but the extraordinary increase in the imports of scammony in the last year of which we have the official details is remarkable, being about treble the ordinary supply. It probably arises from the scientific exertions of the Turkish authorities, and the practical information and instruction which have been diffused among the peasantry.

Opium.—From an examination of the official annual statements of the trade of the United Kingdom for some years past, we are able to trace out accurately our imports of opium from Turkey, and the value; these have been as follows:—

	lbs.	Value.
1866	214,399	£180,001
1867	294,277	248,015
1868	363,249	464,191
1869	230,886	382,471
1870	313,543	452,974

Although the official Board of Trade return, enumerating the principal articles received last year, has been published, the more precise annual statement, which specifies also the minor articles, will not be issued for some months to come.

An interesting monograph on the varieties of opium exhibited in the Turkish department of the last Paris Exhibition, was privately issued by Col. Fayk Bey, director of the central civil and military pharmacy, chemist to the palace, and professor of pharmacology to the imperial faculty of medicine at Constantinople. This document contained much valuable information, being the result of answers to official circulars addressed to the governors of provinces, as to the mode of culture, collection of the juice, manipulation and transformation into cakes, and nature of the commercial transactions at the seats of production. Moreover, a complete analysis was furnished of ninety-two specimens, which were shown.

On the culture and propagation of the plant I need not enter into details, but a few particulars respecting the collection of the inspissated juice may be given. Great care and vigilance are required to seize the proper time, when the bluish-green colour of the capsule begins to change to a golden hue, to incise it horizontally. Leaves of the poppy are first spread on the soil, to receive any of the milky juice which may accidentally drop. In localities subject to frequent showers, the incisions are made in the capsule about daybreak, and the milky juice which oozes forth is collected before noon. In the drier regions, where a more equable temperature prevails, the capsules are incised before sunset, because night favours the secretion of the sap, which is then collected on the following morning. After collecting the juice the capsules are left to ripen, the seed being saved for sowing, or for obtaining oil, and the oil-cake, after expression, is used either for manure or for feeding cattle. A certain quantity of the capsules, either broken and freed from the seeds or entire, are sold for pharmaceutical use. In certain localities the poppy seeds are eaten for pleasure, and sometimes, among those who give way to this practice, a slight narcotic effect is observed.

A deunum of good land (about 1600 square yards), well prepared, will yield from 2 to 2½ okes of opium and 5 bushels of seed. But the yield of both opium and seed varies considerably.

The inspissated juice is collected in earthen, copper or wooden vessels, and a few days later it is moulded or kneaded into shape by the hands, with heat. After exposure for some time to the sun, the lumps or cakes are rolled over *Rumex* seeds, and wrapped in poppy leaves, in which state they pass into commerce. The great variety of shape, size, and appearance of these cakes of opium is remarkable, for each locality seems to have a special type or form of its own.

The cultivator is always under heavy liabilities to speculators and dealers, who purchase his crop in advance, and 18 to 25 per cent. interest is considered moderate. From these factors it passes again through three or four hands before it arrives at the ports of shipment.

The opium obtained from small poppy-heads is the most rich in morphia, and siliceous clayey soils are found to be more favourable to the production of opium than light friable soils.

The following was the export of opium from certain localities in Turkey in the year 1866, which will serve as an indication to the principal seats of production:—

Localities.	Okes.
Ighakli	6,250
Tchol	3,125
Kikler	1,250
Bolvadina	3,125
Hanya	3,125
Sandikli	1,875
Chahvar	6,250
Cheiklou	12,500
Kara Hissar	18,750
Sihanli	7,500
Gueive	2,000
Lefke	200
Gueul Bazar	800
Kara Hissar Sahib	81,250
Kharpout (Malatia)	50
Rhodes	2
Baloukesser	2,000
Angora (Mihalidjik)	2,000
	152,052

As the oke is reckoned at 2¾ lb., this gives about 418,513 lb. of opium, the approximative local value of which was 40,000,000 of piastres.

If the growers were free from the rapacity of the usurer, no more profitable culture could be carried on than opium. Taking the ordinary yield of a deunum of land at 2 okes (5½ lb.) of opium, at the mean price of 230 piastres, and adding 5 bushels of seed worth at least 30 piastres the bushel, this gives a total value of 610 piastres. If from this 200 piastres be deducted for the maximum expense of cultivation, this leaves a profit of 410 piastres (about £4), a higher return than can be obtained from any other culture.

If it were not stated by an officer of the government, we should hardly have credited the extent of adulteration carried on, and which has to be guarded against by the purchaser.

Amongst the adulterating substances enumerated are scrapings and decoctions of the stem and leaves of the poppy, raisins, glucose, the pulp of fruit, the yolk of eggs, wax, marble, powdered bricks, rosin and galipot; all these are called into requisition to render the opium more heavy and to add to its bulk. Often 10 to 12 per cent. of water is added. Of late years one or two large shipping firms have retained chemists to analyse and certify to the quality of the opium they export, which is sold with a guarantee; but the small dealers and local druggists are still subject to all these current frauds.

(To be continued.)

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

SULPHUR PRÆCIPITATUM.—Flowers of sulphur and slaked lime are boiled together with water for some time. The deep yellow liquid is filtered, cooled, diluted with water, and then acidified with hydrochloric acid, which throws down the sulphur in the form of a nearly white precipitate.

The principal changes which occur are exhibited in the two following equations:—

$$\underset{\text{Slaked Lime.}}{3[CaO\,.\,H_2O]} + \underset{\text{Sulphur.}}{5S_2} = \underset{\text{Pentasulphide of Calcium.}}{2CaS_5} + \underset{\text{Hyposulphite of Calcium.}}{CaS_2O_3} + \underset{\text{Water.}}{3H_2O}$$

$$\underset{\text{Pentasulphide.}}{2CaS_5} + \underset{\text{Hyposulphite.}}{CaS_2O_3} + \underset{\text{Hydrochloric acid.}}{6HCl} = \underset{\text{Chloride of Calcium.}}{3CaCl_2} + \underset{\text{Sulphur.}}{6S_2} \quad \underset{\text{Water.}}{3H_2O}$$

In consequence of secondary reactions occurring during the boiling, a little sulphuretted hydrogen is given off when the liquid is acidified. If sulphuric acid is employed instead of hydrochloric acid, a considerable quantity of sulphate of calcium is precipitated with the sulphur.

[§ A greyish-yellow soft powder free from grittiness and from the smell of sulphuretted hydrogen. When heated in an open vessel, it burns with a blue flame and the evolution of sulphurous acid. Entirely volatilized by heat. Under the microscope it is seen to consist of opaque globules without any admixture of crystalline matter.] The tests are designed to show that sulphate of calcium is not present.

Milk of sulphur is usually not entirely soluble in bisulphide of carbon, a small quantity of allotropic sulphur remaining behind.

SULPHUR SUBLIMATUM.—[§ Sulphur prepared from crude or rough sulphur by sublimation.] Sulphur is manufactured chiefly from native sulphur, which is imported principally from Sicily. It is also obtained from iron and copper pyrites, FeS_2 and $FeCuS_2$. Some considerable quantity is also recovered from "soda-waste," the impure sulphide of calcium obtained in the manufacture of carbonate of soda. By exposure to air this substance is partially oxidized and converted into hyposulphite. On the addition of hydrochloric acid, a reaction occurs which results in the precipitation of the greater part of the sulphur.

$$\underset{\text{Unchanged Sulphide.}}{2CaS} + \underset{\text{Hyposulphite of Calcium.}}{CaS_2O_3} + 6HCl = \underset{\text{Chloride of Calcium.}}{3CaCl_2} + \underset{\text{Water.}}{3H_2O} + \underset{\text{Sulphur.}}{2S_2}$$

Native sulphur is purified by distillation into receivers in which it condenses in the liquid state. Solidified in moulds it forms "roll sulphur." To obtain "flowers of sulphur" the vapour is passed into a brickwork chamber in which, in consequence of being cooled suddenly, it is reduced at once to the solid form.

Sublimed sulphur under the microscope will be found to consist of translucent globules which consist of crystals radiating from a centre. Except that it is crystalline, sublimed sulphur agrees in most respects with milk of sulphur.

The impurities which the B. P. tests are intended to provide against are chiefly sulphurous acid and sulphide of arsenic. [§ Does not redden moistened litmus paper. Solution of ammonia, agitated with it, and filtered, does not on evaporation leave any residue.]

Sulphur in its ordinary state is a yellow brittle solid, fusible, volatile, inflammable in the air, soluble in bisulphide of carbon, and in hot benzol and oil of turpentine. Heated to fusion, it solidifies on cooling to a mass of brownish translucent prismatic crystals which rapidly change back again into the ordinary or octahedral form. When melted sulphur is heated considerably above its fusing point, it becomes extremely viscid, and retains this character if suddenly cooled. This plastic form of sulphur is insoluble in bisulphide of carbon, but recovers the crystalline soluble condition in a short time. Sulphur may be made to assume several other "allotropic" forms, which, however, are of less interest.

In most of its combinations sulphur exhibits a bivalent or dyad character, *e.g.*

$$\left.\begin{matrix}H\\H\end{matrix}\right\}S \qquad \left.\begin{matrix}H\\K\end{matrix}\right\}S \qquad \left.\begin{matrix}K\\K\end{matrix}\right\}S \qquad Fe''S$$

Oxides of Sulphur.		Corresponding Acids.
Hydrosulphurous (Schutzenberger)		H_2SO_2
Sulphurous	SO_2	H_2SO_3
Sulphuric	SO_3	H_2SO_4
Hyposulphurous or Sulpho-sulphuric		H_2SSO_3
Disulphuric or Nordhausen sulphuric		$H_2S_2O_7$
Dithionic		$H_2S_2O_6$
Trithionic		$H_2S_3O_6$
Tetrathionic		$H_2S_4O_6$
Pentathionic		$H_2S_5O_6$

There are two compounds of sulphur with hydrogen, corresponding to water and peroxide of hydrogen respectively.

Sulphuretted hydrogen or Hydrosulphuric acid	H_2S
Persulphide of Hydrogen	H_2S_2

With carbon sulphur unites directly at a bright red heat, producing carbon disulphide CS_2, the analogue of carbon dioxide CO_2.

With chlorine, bromine and iodine there are several compounds. Of these, S_2Cl_2 and S_2I_2 are employed in medicine. The former is obtained by passing chlorine over sulphur, and the preparation known as "hypochloride of sulphur" consists of flowers of sulphur impregnated with a small quantity of this compound.

In many compounds sulphur officiates as the representative of oxygen. We have, for instance,

H_2S	corresponding	to	H_2O
H_2S_2	,,	,,	H_2O_2

Sulphuris Iodidum.—Four ounces of iodine and one ounce of sulphur are mixed and melted together in a flask.

The compound possesses very nearly the composition represented by the formula S_2I_2.

Two atoms of iodine	$= 127 \times 2$	$= 254$
Two atoms of sulphur	$= 32 \times 2$	$= 64$

These are nearly the proportions employed by the Pharmacopœia.

The compound gradually loses iodine when kept exposed to the air.

IRON REDUCED BY HYDROGEN.

BY PROFESSOR G. DRAGENDORFF,

(*Dorpat, Russia.*)

It is well known that the preparation bearing this name, as it is found in the market, frequently contains large proportions of triferrotetroxide; nay, that it occasionally consists of this exclusively, so that it yields no effervescence in contact with diluted acids. Sometimes, even when diluted acids develope hydrogen, greyish-black, rounded masses, may be separated from the powder by a sieve, easily recognizable as the above mentioned oxide. The explanation of its presence has long ago been given; a portion of the iron, after reduction, taking up oxygen from the air, while another portion of the oxide may be derived from the incomplete decomposition of the ferric oxide. The first occurs when the iron has not been sufficiently heated during its reduction; the latter, when the supply of hydrogen has been insufficient for perfect reduction.

To obtain a preparation not disposed to the re-absorption of oxygen, I conduct the reduction in an iron tube of an internal diameter of 1·4 inch, heated in a small Paris muffle to a bright white heat, by means of coke and charcoal. Such a furnace, useful also to the goldsmith, should not be wanting in any pharmaceutical laboratory. Connected, by means of a stovepipe, with a well-drawing chimney, sufficient heat can be produced in this furnace to melt silver and copper.

To heat tubes, I cut circular holes in opposite sides of the furnace, into which holes the tubes are placed after the removal of the muffle. In doing other work these holes are closed by means of iron plugs lined with clay.

Another objectionable feature of the commercial ferrum redactum, is the amount of sulphur it contains. It must be conceded that, if the product is to have any advantage over the ordinary powdered iron, it must consist in its freedom from carbon and sulphur, so as to dissolve in the stomach without the development of hydrogen charged with hydric sulphide and carbide. The exhibition of so expensive a preparation as the ferrum redactum, becomes inadmissible when it contains ferrous sulphide, and developes the hydric sulphide upon dissolving. The almost universal existence of this iron contaminated with ferrous sulphide, is best shown by the assertion of one of the largest manufacturers in Berlin, Mr. Schering: "I have never yet succeeded in producing an iron, reduced by hydrogen, free from sulphur."

I would say, that ten years ago such a preparation, free from sulphur, had been prepared in my laboratory by way of experiment; and I take the liberty of publishing my formula for the same, which increases its cost a trifle over the old method.

If we inquire into the origin of the ferrous sulphide in the reduced iron, we may trace it to two different sources, namely, 1. The ferric oxide used for the reduction may be contaminated by sulphates; and 2. The hydrogen employed in the reduction may have contained hydric sulphide.

As to the first point, it is well known how greatly the precipitate of ferric hydrate is inclined to carry down other substances present in the solution. If the precipitate, as frequently happens now, is produced by contact of ferric sulphate with sodic carbonate or with ammonia, it will invariably contain basic sulphate that cannot be removed by simple washing. Even a ferric hydrate precipitated from ferric chloride may contain sulphates, if the muriatic or nitric acids employed in the preparation of the former contained sulphuric acid, or if the sodic carbonate employed in the precipitation contained sulphate.

The sulphate contaminating the precipitate is reduced by the hydrogen to sulphide.

Secondly, it is well known that hydrogen produced by the action of dilute sulphuric acid upon zinc, may be contaminated with hydric sulphide if the temperature during its development surpasses 30° C. This hydric sulphide is generated by the reduction of the sulphuric acid by means of the nascent hydrogen; the former undergoes such a decomposition into sulphur and hydric sulphide under various other conditions.

These observations at once point out the conditions requisite for the production of a pure ferrum redactum, namely, the employment of ferric oxide free from sulphates, and of hydrogen free from hydric sulphide.

The first I obtain by heating ferrous oxalate in an iron dish with access of air: the oxalate is produced by precipitation of ferrous chloride with neutral potassic oxalate; and the ferrous chloride is made by dissolving iron nails in pure muriatic acid.

During the disengagement of hydrogen the vessel is to be placed in cold water, the sulphuric acid being diluted with eight parts of water. Should the reaction cease, dilute, but never concentrated, sulphuric acid should be added. The hydrogen is next passed through two tubes, one of which is filled with small pieces of pumice-stone, moistened with a solution of plumbic nitrate, and the other with pieces of potassic hydrate. I must add, that by passing the hydrogen over hot ferrous oxalate I obtained pure iron; but the other method is generally preferable for the preparation of ferrum redactum,—first, because, in the shape of the compact oxide, more iron can be placed in the tube than when the ferrous oxalate is used; and secondly, because I fear, though it has not occurred to me in practice, that during careless operations part of the carbon derived from the oxalate may remain behind as ferrous carbide. The latter subjected to the action of acid would again develope badly-tasting hydrogen.—*The Chicago Pharmacist.*

PHARMACOGNOSTICAL NOTES.—AMERICAN INDIGENOUS PLANTS.

BY JOHN M. MAISCH.*

Many interesting questions connected with the United States indigenous materia medica require investigation, and it is in most cases not easy to obtain the desirable information. The various inquiries instituted within the past few years, in different sections of the States, into the statistics of this branch of the drug trade have resulted in total failures; and, except to the initiated, very little is known of the localities where many of the staple articles of the indigenous materia medica are collected for the general commerce, the information being usually limited to the geographical section of the country. The difficulties encountered in such investigations have been well pointed out by Mr. C. Lewis Diehl, in a paper published in the Proceedings of the American Pharmaceutical Association, 1870, p. 137. The knowledge we possess on this particular point appears merely to indicate that the wholesale market has now to depend on the Southern, South-Western and Western States for a supply of drugs which were formerly supplied in sufficient quantities by the Eastern and Middle States. While this may undoubtedly be in part accounted for by the increased demand, it must be also to some extent due to injudicious collection, whereby some medicinal plants have become nearly or entirely extinct in certain localities where formerly they were frequently met with.

The same cause appears to have had already similar results in some Western localities. In Professor Diehl's paper, cited above, we find the following passage, which seems to point in this direction:—"Formerly there was a lively trade in indigenous drugs in New Albany, Ind. (gathered among a range of hills known as 'the Knobs'), but such is not now the case, and the drugs gathered in its neighbourhood find their markets no further than our city (Louisville, Ky.)." Apparently the same wasteful practice, satisfied with the results of to-day, without looking to the demands of the morrow, prevails among the drug gatherers of North as in South and Central America, and it is not improbable that the time may not be far distant when a few of the leading drugs may require to be cultivated to ensure a full and continuous supply of the market.

Although many of the indigenous plants have been used in domestic and in regular practice, the use of some seems to be confined altogether to certain localities, beyond which their medicinal properties are unknown or not appreciated. It would be very interesting to obtain reliable information concerning them.

The following notes are intended to direct attention to a few articles of the indigenous materia medica, nearly all of which deserve to be further investigated:—

Cypripedium.—The secondary list of the Pharmacopœia of the United States directs the rhizome and rootlets of *Cypripedium pubescens*, Willdenow. Under the common names of ladies' slipper and American valerian, two entirely distinct rhizomes, with the rootlets attached, are met with in commerce, both of monocotyledonous origin. The only species of this genus which I have met with in the neighbourhood of Philadelphia is *Cypripedium acaule*, Aiton, the radical portion of which has not been observed by me among the commercial ladies' slipper root. The officinal species appears to grow as far south as Georgia, and west to Wisconsin. Gray † states that it is common northward and westward, and southward in the Alleghanies. Dr. Porcher ‡ says it occurs near New-

* Read before the Philadelphia College of Pharmacy, April 16th.

† 'Manual of the Botany of the Northern United States.'

‡ 'Resources of the Southern Fields and Forests, p. 603.'

born. Dr. Darlington * mentioned, twenty years ago, that it was formerly frequent in Chester county, Pa., and it is probable that the plant is now of rarer occurrence yet.

Another species, which, like the one mentioned, bears flowers with yellow lips, is *Cypripedium parviflorum*, Salisbury, which appears to be most common west; though usually smaller than the former, it attains the height of 1 to 2 feet, the two species appearing to pass into each other (Gray). *Cypripedium candidum*, Muhlenberg, and *C. spectabile*, Swartz, both with white-lipped flowers, occur mainly in the Alleghanies and west thereof, and it is not impossible that they may furnish a portion of the commercial root, while *C. arietinum*, R. Brown, the smallest species, occuuring in Canada and the northern border States, is probably not collected.

For a number of years past I have been endeavouring to procure the four species first mentioned, with root and flowers, but have been unsuccessful. Mr. F. C. Weber, while at New Albany, Ind., last year, tried to aid me in my endeavours, and obtained from an old herbalist there the information that *C. pubescens* and *parviflorum*, both of which plants he described correctly, are collected there indiscriminately. At Mr. Weber's request, he collected one plant with the roots and the green fruit, the only one, he stated, he could find, which he palmed off as the first-named species, but which was promptly recognized by me as *Uvularia perfoliata*, L. This deception was doubtlessly purposely attempted.

No better success attended my inquiries of dealers in indigenous drugs, who appear to sell these goods without questioning their identity, relying upon the statements of the Western collectors. The only way to arrive at correct results is to have complete specimens of the different species collected, so that their roots may be compared with the commercial article.

Cephalanthus occidentalis, L., *Rubiaceæ*, button-bush, or pond-dogwood, is a shrub 5 to 10 feet high, common throughout Canada and the United States in swamps and on the margin of ponds and brooks. The bark has been repeatedly recommended as an expectorant useful in consumption, but I believe has been abandoned, though it may be used yet as a domestic remedy. Last fall a sample of the bark, with a flowering branch, was received from Texas, where a gentleman claimed that the bark had wonderful curative properties; of what character was not stated. If we may judge from the slight bitter taste, which is destitute of acridity, it may probably possess tonic properties.

Ilex Cassine, L., *Aquifoliaceæ*, grows near the coast from Virginia southward, and is known there under the names of cassena, yeopon, yupon or yaupon. It appears to have been held in high repute by the aborigines, and to be still used to a considerable extent near the North Carolina coast.

Dr. Porcher† states that the Creeks employed it, according to Elliott, at the opening of the councils sending to the seacoast for a supply; they considered it one of their most powerful diuretics. The inhabitants of North Carolina purify brackish water by boiling in it cassena leaves. In North and South Carolina much use is made of the leaves for making tea. The leaves act as a powerful diuretic, and are employed in calculous, nephritic diseases, diabetes, gout and small-pox. The so-called black drink of the Indians, which in its effects resembled opium, was believed by some to have been made from these leaves, but by other writers is referred to various unknown roots.

In a letter written three years ago, Mr. Chas. K. Gallagher, of Washington, N.C., to whom I am indebted for some of the leaves, states that they are used extensively along the eastern coast of that State, and that they are cured for use by heating in ovens with heated stones, and constantly stirring during the process, as practised by the Indians.

The cassena is an evergreen shrub, attaining a height of 10 to 15 feet; the leaves are alternate, coriaceous, short petiolate, about an inch long, varying in shape from roundish oval to lanceovate, obtuse and slightly emarginate, crenate with a minute spine inserted near the base of each crenature, smooth on both sides and shining above; their taste is mildly astringent and tea-like, scarcely bitterish.

It would be very interesting to ascertain whether cassena contains caffeine, like the so-called Paraguay tea, which is obtained from *Ilex paraguayensis*, Lamb.

Artemisia Ludoviciana, Nuttall, *Compositæ*, was sent to me two years ago, from Kansas, where a package of it had been received by an army officer from Colorado, with the statement that it would "make the hair grow," if applied in a state of infusion. The plant is indigenous to North America, and grows from the shores of Lake Huron and Michigan south-westward to Missouri and westward to the Pacific Ocean. It is from two to four feet high, branched; leaves lanceolate, sessile and entire above, the lower variously toothed, canescent on both sides, with a dense, closely adpressed wool; heads small, ovoid, nearly sessile, crowded in dense, somewhat leafy panicles; receptacle smooth. The odour reminds of wormwood, but is much weaker; the taste is similar, though but slightly bitter.

The plant has probably tonic properties, but appears not to deserve a place alongside the numerous bitter aromatic tonics at the present time medicinally employed.

Pycnanthemum linifolium, Pursh., *Labiatæ*, in some places called Virginia thyme, was sent to me a year or two ago, as the remedy successfully used by an empiric in Montgomery county, Pa., in cases of hydrophobia. It is hardly credible that this plant could be of any value in this fearful disease, possessing, as it apparently does, merely somewhat stimulating and diaphoretic properties, like most species of this order, in consequence of the small quantity of volatile oil which it contains. It is smooth throughout, about 1½ to 2 feet high, with the linear and sessile leaves ½ to 2 inches long, rigid, entire, three-nerved, often crowded in small axillary fascicles; the branches are erect and form a rather dense corymb; the flowers terminate the branchlets and are crowded into hemispherical heads, supported by imbricated ciliate bracts, which, like the awl-shaped calyx teeth, are rigid and sharply pointed; corolla whitish or pinkish, dotted on the inside.

Pycnanthemum incanum, Michaux, mountain mint or wild basil, is also called horsemint in some countries of Pennsylvania where *Monarda punctata*, L., does not occur, in place of which it is used. The two plants are easily distinguished, the bracts of the former being linear, almost subulate, while those of the *Monarda* are leaf-like, and of a yellow and reddish colour. The medicinal properties of both are probably identical.—*American Journal of Pharmacy.*

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

(*Continued from page* 922.)

II. *Action of Hydrochloric Acid on the Polymerides of Codeia.*

(*a*). *Tetracodeia.*—Tetracodeia hydrochlorate was boiled for six hours with a large excess of strong HCl; no perceptible evolution of methyl chloride took place; and on examining the resulting product no change was found in the ratio of carbon to chlorine. Hence no substitution of Cl for OH had taken place, and apparently no action at all had ensued.

(*b*). *Tricodeia.*—Tricodeia hydrochlorate was heated to 100° for $1\frac{1}{4}$ hours with a large excess of strong HCl; on adding water to the product, a tarry substance was precipitated, whereas the original tricodeia hydrochlorate is readily soluble in dilute HCl; precipitated by Na_2CO_3, and the precipitate exhausted with ether, a a viscid non-crystalline hydrochlorate was obtained on agitation of the ethereal extract with HCl. The reactions of this product appear to be identical with those of tricodeia, excepting that the reddish-purple tinge with Fe_2Cl_6 appears instantaneously instead of only after standing a short time. Dried at 100°,

0·3070 grm. gave 0·756 CO_2 and 0·185 H_2O.
0·2480 „ 0·1150 AgCl.

	Calculated.		Found.
C_{108}	1296	68·03	67·16
H_{120}	120	6·30	6·69
Cl_6	213	11·18	11·48
N_6	84	4·41	
O_{12}	192	10·08	
$C_{108}H_{114}N_6O_{12},6HCl$	1905	100·00	

Hence this product has been formed by the reaction

$$C_{108}H_{126}N_6O_{18},6HCl = 6H_2O + C_{108}H_{114}N_6O_{12},6HCl,$$

and has the composition of a polymeride of "apocodeia." From the great similarity observed between this product and "apocodeia" made by Matthiessen and Burnside's process,* it appears probable that the product of the action of zinc chloride on codeia is a mixture of bodies of general formula $(C_{18}H_{19}NO_2)n$ nHCl, in which the derivative where n=6 greatly predominates; experiments on the action of zinc chloride on morphia now in progress in conjunction with Herr L. Mayer indicate that mixtures are obtained in this case also.

(*c*.) *Dicodeia.*—When pure dicodeia hydrochlorate is heated to 100° for one hour with a large excess of HCl, a change is produced expressible by the equation

$$C_{72}H_{84}N_4O_{12},4HCl + HCl = C_{72}H_{83}ClN_4O_{11},4HCl + H_2O,$$

which shows that the formula of this polymeride contains at least C_{72}. Na_2CO_3 throws down from the product a voluminous white precipitate, which differs in appearance slightly from that of dicodeia, and turns green by exposure to air; ether dissolves this precipitate, and on agitation with HCl a viscid hydrochlorate is obtained which does not crystallize, but dries up to a gum. Fe_2Cl_6 gives a brown-purple tint, NO_3H a blod-red, and

$$K_2Cr_2O_7 + SO_4H_2$$

a lighter blood-red, none of which reactions occur with the original dicodeia. Dried at 100°,

0·3200 grm. gave 0·737 CO_2 and 0·189 H_2O.

III.—*Action of Hydriodic Acid and Phosphorus on the Polymerides of Codeia.*

(*a*). *Dicodeia.*—When pure dicodeia is dissolved in a large excess of strong hydriodic acid (55 per cent. HI) and heated, together with a piece of phosphorus, to ebullition until the boiling-point rises to 120°, methyl iodide is given off and a considerable quantity of phosphoric acid formed. The product, filtered through asbestos and precipitated with water, yields snow-white flakes that become yellow by exposure to air, and melt to a colourless oil at 100° when moist, although they do not fuse at that temperature when thoroughly dried. Dried at 100°,

0·3155 grm. gave 0·5620 CO_2 and 0·1460 H_2O.
0·1895 „ 0·1190 AgI.

	Calculated.		Found.
C_{136}	1632	48·45	48·58
H_{161}	161	4·78	5·14
I_9	1143	33·94	33·92
N_8	112	3·33	
O_{20}	320	9.50	
$C_{136}H_{153}IN_8O_{20},8HI$	3368	100·00	

Hence this substance is formed by the reaction—

$$2C_{72}H_{84}N_4O_{12},4HI + 20HI =$$
$$= I_8 + 4H_2O + 8CH_3I + C_{136}H_{153}IN_8O_{20},8HI.$$

The physical properties of this substance are almost identical with those of the bodies of analogous constitution (containing C_{136}) formerly obtained from both codeia and morphia; carbonate of sodium throws down a precipitate almost insoluble in ether, showing that polymerization to the tetra-series has taken place; agitated with a large bulk of ether, this precipitate furnishes an extract, which, on agitation with dilute nitric acid and boiling with $AgNO_3$ and NO_3H of the nitrate thus obtained, yields a precipitate of AgI, showing that iodine is contained in the precipitated base, The substance itself boiled with $AgNO_3$ and HNO_3 produces a deep orange-coloured liquid, intermediate in tint between the blood-red produced by the derivatives of polymerized $C_{17}H_{19}NO_3$, and the deep yellow by those of polymerized $C_{17}H_{21}NO_3$, a result confirmatory to some extent of the formula deduced from the analysis, this being capable of representation as—

$$8(C_{17}H_{20}NO_3) + 9HI - 4H_2O.$$

From this it appears pretty evident that the formulæ hitherto attributed to the tetra bases (containing $C_{68} - C_{72}$) are only half the true ones, which contain $C_{136} - C_{144}$.

(*b*). *Tetracodeia.*—On treating tetracodeia in the same way and continuing the ebullition until the temperature reaches 130°, a brown syrupy liquid is finally obtained, which yields, on filtration through asbestos and precipitation with water, a yellow brittle tar not fusible at 100° when quite dry; methyl-iodide is produced in quantity during the action, but only traces of phosphoric acid, and this probably by atmospheric oxidation. Dried at 100° the tar gave these numbers:—

0·3660 grm. gave 0·621 CO_2 and 0·149 H_2O.
0·5520 „ 0·363 AgI.

	Calculated.		Found.
C_{136}	1632	46·31	46·27
H_{158}	158	4·48	4·53
I_{10}	1270	36·04	35·54
N_8	112	3·18	
O_{22}	352	9·99	
$C_{136}H_{150}I_2N_8O_{22},8HI$	3524	100·00	

Hence this substance is formed by the reaction—

$$C_{144}H_{168}N_8O_{24},8HI + 10HI =$$
$$= 8CH_3I + 2H_2O + C_{136}H_{150}I_2N_8O_{22},8HI.$$

NO_3H and $AgNO_3$ give a blood-red colouration with this product, showing, as the analytical numbers indicate, that it is derived from polymerized $C_{17}H_{19}NO_3$, and not from polymerized $C_{17}H_{20}NO_3$, or $C_{17}H_{21}NO_3$.

The foregoing results show that the methyl group in codeia is unaltered during the polymerization to dicodeia and to tetracodeia, and furnishes another proof of the conclusion come to in Part IV., § 2, that the addition

* Proc. Roy. Soc., vol. xix. p. 71.

of H_2 for C_{17}, when HI and P act on morphia or codeia, takes place *before*, and not after, the final polymerization; even polymerization to dicodeia could not precede this addition of of H_2, as the product obtained from that polymeride has only H added on for C_{17}.

The following formulæ show clearly the difference in the action of hydriodic acid and phosphorus on codeia and its polymerides.

Alkaloid.	Temperature.	Formula of Product.
Codeia ...	100°	... $8(C_{17}H_{19}NO_3+H_2)+12HI$.
,, ...	110°–115°	... $8(C_{17}H_{19}NO_3+H_2)+12HI-4H_2O$.
,, ...	up to 130°	... $8(C_{17}H_{19}NO_3+H_2-O)+12HI-4H_2O$.
Dicodeia	up to 120°	... $8(C_{17}H_{19}NO_3+H)+9HI-4H_2O$.
Tetracodeia	up to 130°	... $8(C_{17}H_{19}NO_3)+10HI-2H_2O$.

From which it is clear that dicodeia is intermediate between tetracodeia and ordinary codeia. From the fact that 4HI for 8 (C_{17}) are added on in the case of the first product *before* the elimination of $4H_2O$, as in the second substance in the list, it may be inferred that the action is not a true substitution of iodine for hydroxyl; analogous facts have been observed in the chlorinated substances obtained by the action of HCl on codeia and morphia, the first action being apparently a direct *addition* of the elements of HCl, the subtraction of the elements of H_2O taking place at a later stage.

PHENOMENA ASSOCIATED WITH THE HYDROGEN FLAME.

BY W. F. BARRETT.

In a recent number of 'Nature,' * Mr. W. F. Barrett has recorded some extremely interesting researches upon some phenomena associated with the hydrogen flame, one of the results of which appears to be that the statement current in the manuals of chemistry, that hydrogen burns with a blue flame, will in future have to be altered. The following is a sketch of some of the phenomena met with, but we must refer our readers to the paper itself for further details and the conclusions which the author draws from his experiments.

For the purpose of studying these phenomena free from disturbing causes, Mr. Barrett recommends that the gas should be purified by passing into a gasholder through a solution of potash, and then through a solution of perchloride of mercury or nitrate of silver; that it should be conducted to a platinum, or, preferably, a steatite jet, through red or black india-rubber tubing, and that it should be burnt in a perfectly dark room, amid calm and dustless air. The flame so obtained is a faint reddish-brown colour, invisible in daylight, but in a dark room showing a stream of luminosity more than six times longer than the flame of the burning hydrogen.

In many cases, when solid bodies, such as marble, chalk, granite, gypsum, etc., are brought into contact with the flame, phosphorescent effects are produced. Sand-paper gives a vivid green phosphorescence, showing a perfect section of the hollow flame, and lasting several seconds. No such effect is produced by coal-gas or olefiant or marsh-gas, but oxygen given through coal-gas shows it well.

One remarkable phenomenon, which has been studied also by M. Wurtz, is the deep blue and glowing image, the exact size and shape of the hollow flame, that instantly appears upon such an object as a white plate or block of marble when brought into contact with the flame. This effect ceases immediately upon the removal of the flame; it also becomes less distinct, and finally ceases, if the flame be directed repeatedly to the same spot. After many experiments, Mr. Barrett arrived at the conclusion that this phenomenon was in every case due to the presence of sulphur. It does not occur when a chemically clean surface is used. After such a surface has been exposed a short time to London air, which contains sulphate of ammonia, it is produced; but not when the surface is simply exposed to country air, or kept under cover. To sulphur, indeed, arising from various sources, such as vulcanized tubing or the decomposition of the sulphuric acid, he attributes the blue colour generally associated with the hydrogen flame.

As an instance of the delicacy of the hydrogen flame as a test for detecting the presence of sulphur, Mr. Barrett states that although pure precipitated silica gives no blueness with the flame, yet if one grain of milk of sulphur be mixed with five hundred grains of silica, and one-hundredth of a grain of this mixture be thrown on the surface of pure water or chemically clean platinum foil, the blue colour is produced upon bringing the hydrogen flame in contact with it. The fingers, too, immediately after washing, show no colour if brought for a moment into the flame; but if they touch a white india-rubber tube ever so lightly, they will show a vivid blueness, and any substance with which they come in contact will show traces of it. Some sulphates and sulphides,—sulphate of ammonium or alum, for instance,—show the blueness, and are evidently decomposed by the flame; sulphate of soda does not. Sulphuric acid gives a splendid brilliant and persistent blue.

The presence of the least trace of phosphorus is revealed by the production of a vivid green light. Tin and its alloys give a fine scarlet colour; or if there be a trace of sulphur, a lovely purple. If phosphorus also be present, there may be obtained a green belt encircling a rich blue, then a purple zone, and finally a glowing scarlet at the root of the flame. These colours are not imparted to the flame, but occur on the surface; neither are they produced when the combustion of the hydrogen is complete, as in the upper part of the flame.

With gases, the result is different, the whole flame being tinged with the colour imparted to it. A mere trace of hydrochloric acid gas imparts a reddish brown colour; ammonia imparts a yellow colour, and burns freely. Carbonic acid gives a lilac tinge, probably due to its decomposition, and the production and combustion of carbonic oxide.

The author thus briefly sums up the results of his experiments:—

"1. That the combustion of hydrogen exhibits some physical peculiarities, and produces phosphorescence on many substances with which it comes in contact.

"2. That the blueness so often seen in a hydrogen flame is due to the presence of sulphur, derived either from the vulcanized rubber tubing, or from atmospheric dust, or from the decomposition of the sulphuric acid spray from the generator.

"3. That a flame of hydrogen forms an exceedingly delicate re-agent for the detection of sulphur or phosphorus, and possibly also of tin.

"4. That many sulphates, and also carbonic acid, are apparently decomposed by a hydrogen flame.

"5. That a hydrogen flame is further a test for the presence of some gases, notably carbonic acid.

"6. That these results are capable of practical application."

* 'Nature,' April 18th, 1872, p. 482.

METROPOLITAN CHEMISTS' DEFENCE ASSOCIATION.

The business of the above Association was finally concluded on Wednesday last, at the Covent Garden Hotel, by the presentation of an elegant work of art to Mr. E. B. Vizer. The following inscription, borne on one of its panels, expresses the feelings of its donors:—

"Presented to E. B. Vizer, Esq., by his fellow committeemen of the Metropolitan Chemists' Defence Association, and a few friends, as a trifling acknowledgment of his efficient services as Secretary."

It was at first intended to limit the list of contributors strictly to the members of the committee; but a few other gentlemen, who had come into contact with Mr. Vizer, and who greatly appreciated his character and his labours, had insisted on being permitted to add their names.

The Pharmaceutical Journal.

SATURDAY, JUNE 8, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

SCIENCE IN ENGLAND.

OF the hundreds of thousands who overran the downs at Epsom last week, or the millions for whom the exciting events of the Derby Day have an all-absorbing interest, probably not half-a-dozen were even aware, or would have cared a button if they had been told, of the different kind of festival which was being held in the metropolis on Thursday evening, when the FARADAY Lecture was delivered in the theatre of the Royal Institution.

When FARADAY died, the Chemical Society instituted a lecturership to be held during three years by some foreign chemist of distinction, under the sole condition that he should deliver during his tenure of office a discourse upon some branch of chemistry, or upon some topic relating to chemistry, to be determined upon by himself. Three years ago the inaugural lecture was given by DUMAS, and a finer piece of eloquence was probably never listened to. His speech, however, possessed more of the character of a funeral oration, pronounced as it was within a comparatively short period of the death of the great philosopher. No more appropriate place could have been selected for its delivery than the theatre of the Royal Institution, within the walls of which all FARADAY'S great discoveries had been accomplished.

On the present occasion Professor CANNIZARO, of Palermo, was the lecturer, and received the FARADAY Medal.

The subject he had selected, "The Teaching of Chemistry in the Universities," was one which, at the present time, possesses considerable interest as bearing in an important degree upon the progress of Science in Great Britain.

Dr. FRANKLAND in his presidential address to the Chemical Society, and in evidence before a Royal Commission, has lately been complaining bitterly of the decline of scientific discovery in England. He attributes it in great part to the fact that in the examinations for degrees in Science in the English Universities, candidates are not required to give evidence of having performed original work, or of possessing special aptitude for this kind of study. In making these sweeping statements, however, we consider that Dr. FRANKLAND is not doing justice to the Universities, and especially the University of London, which has been labouring earnestly and successfully for years past to elevate the character of the science teaching in this country. Moreover, it seems to us that he by no means strikes at the real root of the evil. It is true that there has been for some time past but little activity in the prosecution of chemical research, and that the number of papers published annually by the Chemical Society is far from proportionate to the increased number of Fellows. But the fault does not lie with the younger chemists, who, as a rule, are fully occupied with the pressing business of getting a living, and have little or no leisure, however much their inclination may be, to devote to pure, which means unremunerative, science. The blame attaches to those men who, occupying high positions, with ample means and abundant leisure if they choose to make it, yet allow themselves to be wholly absorbed by pursuits for which other men would be equally well adapted. They thus not only do not themselves contribute to the advancement of science, but set before their juniors the baneful example of that "ambition of preferment for its gold" by which the whole scientific community is demoralized.

We by no means question the right of every one to the exercise of his abilities in the manner he chooses; but at the same time we hold that this right is limited by the obligations attaching to the higher offices which are attainable by scientific men, and we consider it to be the duty of those holding prominent and lucrative positions to sustain and justify their pre-eminence as representative men by continued research and contribution to the advancement of science.

From another point of view, this duty is especially incumbent upon all chemists holding the position of teachers. In nine cases out of ten, the man who does no experimental work does not read. He thus knows nothing of the progress of science; and, exhibiting none of that enthusiasm which is above all things essential to secure the attention of an audience, he is unable to maintain the interest of his pupils in the subject he pretends to teach. On the Continent, and particularly in Germany, it is otherwise. There the publication of original memoirs by a professor is almost a condition of his retaining his chair; and certainly a want of activity in this respect would influence very seriously his social position as well as his professional career.

FARADAY, in honour of whose memory the assembly of Thursday evening was met together, spent his life in searching out the secrets of nature. It was enough for him that he possessed necessaries; pleasures and luxuries he looked for in his work, and who shall say that he did not find them?

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

June 5th, 1872.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Brown, Frazer, Hampson, Haselden, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

Mr. A. F. Haselden was called to the chair, and took the same accordingly.

The minutes of Council of the 1st and 15th ult. were read and confirmed.

In reply to a question by Mr. Sutton respecting the re-admission of members on payment of subscriptions in arrear, the Secretary said that a circular was sent to all local secretaries about the middle of April, asking for a list of those who had not paid, and accompanied by an extract from the bye-laws. He should much like the accounts of all local secretaries with him to be settled up to the end of March; so that he could then see who were in arrear, and communicate with them direct; and there would be no excuse for members saying they had not had notice. It happened sometimes that local secretaries delayed sending up the subscriptions, and, in consequence, he occasionally got into trouble through applying for subscriptions which had been already paid. He should, therefore, prefer that the local secretaries and collectors cease to receive subscriptions at the end of March, and that the responsibility of collecting the arrears should be left with him.

Mr. Sutton said he, as a local secretary, declined to collect subscriptions, as it took a greal deal of time, and sometimes caused dissatisfaction.

The Secretary said he thought local secretaries might be relieved of some of their duties, particularly that of applying for subscriptions.

Mr. Atherton thought it would be a good plan to request members to forward their subscriptions by a certain date to the local secretary.

The Secretary said he should have no objection to this, if the Council approved.

Election of Officers.

The election of President for the ensuing year was then proceeded with by ballot, the result being that Mr. A. F. Haselden was re-elected unanimously.

Mr. Haselden said: Gentlemen, having again been unanimously elected to be your President, I must say the confidence therein implied is particularly gratifying to me, not so much for the honour itself, although I am a little proud of it, as for the handsome manner in which you have conferred that honour. Permit me to say that whatever success I may have attained during the past year as your Chairman, has been greatly due to the kindness, consideration and support which I have at all times received from you. Under similar conditions I trust that I may be able to fill the chair for another year with satisfaction to you and credit to myself.

Mr. Wm. Scott Brown, of Manchester, was elected Vice-President. He said he should have much preferred the selection should have fallen upon some one else, as he feared he might not be able to attend with sufficient regularity; but feeling that, whilst Mr. Haselden had health and strength, his position would be simply an honorary one, he had much pleasure in accepting the compliment.

Mr. Thos. Hyde Hills was unanimously re-elected Treasurer.

Elias Bremridge was reappointed Secretary and Registrar, and Richard Bremridge, Assistant-Secretary and Deputy-Registrar.

Elections.

Honorary Members.

The following gentlemen were elected Honorary and Corresponding Members of this Society:—

Professor John Hutton Balfour, of Edinburgh.
Professor A. Crum Brown, of Edinburgh.
Professor Friedrich August Flückiger, of Bern.

Members.

The following registered chemists and druggists were elected members of the Society:—

Alcock, Walter.............Sheffield.
Beaumont, Charles F. J. B..St. Mary Cray.
Fitch, William Bowers ....74, Edgware Road.
Grime, Thomas............Over Darwen.
Heathcoat, Thomas.........West Hackney.
Johnson, Joseph ....Kilburn.
Shepherdson, Welburn......Hull.
Steel, Thomas.............Barrow-in-Furness.

On the question being put whether any member of Council were acquainted with a gentleman who had applied for membership, some discussion arose as to the mode of electing members.

Mr. Radley said he had heard complaints by examined members that others had been admitted to membership who were not properly qualified. Two or three gentlemen had been elected in a town with which he was acquainted, who had not served their apprenticeship, and who were not generally recognized by their fellow-townsmen as genuine chemists and druggists. A short time ago he had been requested by a wholesale house to recommend a man for election of whom he knew nothing; and on inquiry, he found that he had not been apprenticed, but had been a working man who had got on, and gone into the business. He suggested that when the names of country gentlemen were proposed, the Local Secretary should be written to, and he would, no doubt, be able to obtain reliable information as to the position and character of the person named. There were many men who would be very glad to pay the entrance fee and subscriptions for the privilege of calling themselves members of the Society.

The President said that by the Act of 1868, under certain conditions, chemists and druggists who had been in business before that date became eligible for membership, and unless there were some valid objection the Council could hardly fail to elect them. There were cases where persons were elected who afterwards had to be removed, but if gentlemen were recommended by an established wholesale house, and proposed and seconded by members of Council they ought to be elected.

Mr. Hampson thought they should be as liberal as possible in electing members, and it did not at all follow that a man was not eligible as a member because he had not served an apprenticeship. They ought not to throw any obstacle in the way of chemists and druggists becoming members.

Mr. Williams agreed that there should be no attempt to draw any line which would prevent chemists from becoming members.

Mr. Urwick thought it would be advisable to communicate with the Local Secretary in the case of proposed members from the country, and that the Secretary should do so.

Mr. Brown said every precaution ought to be taken to prevent unsuitable persons being elected, but he did not think that examined members had any just ground for complaint; nor ought the line to be drawn too strictly. He was quite sure that every means had been taken to ascertain if the gentlemen whose names were proposed were suitable, but he must protest against the idea that members of the trade were conferring any benefit on the Society by paying an entrance fee and becoming members. There would be no difficulty in any properly qualified man finding means to get himself recommended by a member of Council.

Associates.

The following, having passed their respective examinations, were elected "Associates in business":—

MINOR.

Stanley, Herbert .... Leamington.

MODIFIED.

Hickman, Frederick .... Newbury.
Powell, Edward Foley ...... Birmingham.

The following, having passed their respective examinations, were elected Associates:—

MAJOR.

Joule, John Samuel .... Buxton.

MINOR.

Allison, Reuben .... Glantwrch.
Appleton, Arthur James...... Attercliffe.
Brown, George Matthew .... Landport.
Crisp, Frederick Arthur ...... Clapham.
Dismorr, Henry .... London.
Francis, William Henry ...... Diss.
Harry, Seth .... Gravesend.
Hilston, David P. .... Lanark.
Lindsay, Robert .... Lasswade.
Maurice, James .... Cardigan.
Munro, John Morrison ...... Aberdeen.
Partridge, Samuel .... Dudley.
Saunders, Thomas Bealby .... Cheltenham.
Savell, Edward Pearce ...... Southampton.
Stewart, Edward Hinton .... Tiverton.
Verity, William .... Northampton.
Walden, Robert Woolley .... Newark.
Walton, William Henry...... Croydon.
Young, John .... Edinburgh.

MODIFIED.

Burdon, Thomas Austin ...... Durham.
Sheel, Robert, jun. .... Rugeley.

The Secretary presented a list of 35 members and four "Associates in business" who had paid their subscriptions subsequently to the 30th April, and it was

Resolved — That they be restored to their former status on payment respectively of a nominal fine of one shilling.

The following, being duly registered as pharmaceutical chemists, were respectively granted a diploma stamped with the seal of the Society:—

Henry, James Hay .... Macduff.
Kendall, Edward Basnipp .... Nottingham.
Laugher, William .... West Bromwich.
Sant, George .... Atherstone.

APPOINTMENT OF COMMITTEES.

The following Committees were appointed:—

General Purposes—The whole of the Council; to meet as occasion requires.

Finance—Messrs. Betty, Greenish, Hampson, Owen and Urwick; at 11 A.M. on the day preceding the Meeting of Council.

Library, Museum and Laboratory — Messrs. Betty, Bottle, Greenish, Hills, Sandford, Schacht and Williams; at 11 A.M. on the second Wednesday of each month.

House—Messrs. Betty, Bottle, Greenish, Hills, Sandford, Schacht and Williams.

Benevolent Fund—Messrs. Betty, Greenish, Hampson, Owen and Urwick.

Parliamentary—Messrs. Atherton, Betty, Bottle, Hills, Hampson, Owen, Sandford, Savage, Shaw and Williams; with power to add to their number.

Provincial Education — Messrs. Atherton, Baynes, Betty, Frazer, Mackay, Radley, Sandford, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams; to meet when required on the day preceding the meeting of Council, at 4 P.M.

On the appointment of the Provincial Education Committee,

Mr. SCHACHT suggested that the word "provincial" should be omitted, in order that the question of education generally might come under the cognizance of the committee. It was clear that if the subject of provincial education were gone into with anything like a large spirit, they would touch interests that were not altogether provincial. London was a large province in itself; and many operations which they might think it desirable to inaugurate would affect portions of London. There were other subjects connected with education, as carried on in that building, which he thought would be all the better, at any rate, for ventilation.

The PRESIDENT said the subject was a large one, and he did not think it could be satisfactorily disposed of on that occasion. He thought the best way would be for the committee to meet under its ordinary name; and then, after full consideration, if they thought right, they could come before the Council with any suggestion as to the alteration of the name or otherwise.

The committee was then appointed, as above.

On the motion for appointing Boards of Examiners,

The PRESIDENT announced that Mr. Hanbury desired to withdraw, as he considered there should be changes in the board from time to time.

BOARDS OF EXAMINERS.

England and Wales.

The following *twelve* pharmaceutical chemists were elected and appointed Examiners for England and Wales for the ensuing year, subject to the approval of the Privy Council:—

Allchin, Alfred .... London.
Barnes, James Benjamin .... London.
Bird, Augustus .... London.
Carteighe, Michael .... London.
Cracknell, Charles .... London.
Davenport, John Thistlewood .... London.
Edwards, George .... Dartford.
Gale, Samuel .... London.
Garle, John .... Bickley, Kent.
Ince, Joseph .... London.
Linford, John Samuel .... London.
Southall, William .... Birmingham.

Scotland.

The following *eight* Pharmaceutical Chemists were appointed Examiners for Scotland for the ensuing year, subject to the approval of the Privy Council:—

Ainslie, William .... Edinburgh.
Aitken, William .... Edinburgh.
Buchanan, James .... Edinburgh.
Gilmour, William .... Edinburgh.
Kemp, David .... Portobello.
Kinninmont, Alexander ...... Glasgow.
Noble, Alexander .... Glasgow.
Young, James Robert .... Edinburgh.

The President and Vice-President are on all Committees *ex officio*, and on the respective Boards of Examiners in London and in Edinburgh.

EDITOR AND SUB-EDITOR.

Dr. Paul was reappointed Editor of the Society's Journal for the ensuing year.

Mr. Passmore was reappointed Sub-Editor of the Society's Journal for the ensuing year.

LOCAL SECRETARIES.

On the motion for the appointment of local secretaries,

The SECRETARY said there was great want of interest throughout the country as regards the returns for the nomination or appointment of Local Secretaries; for in no less than 70 towns, entitled by the number of members to have a Local Secretary, there had been no return whatever.

The Council then elected Local Secretaries for the ensuing year. *The list will be published next week.*

Conversazione.

Resolved—That the best thanks of this Council be given to their Lordships the Committee of Council on Education for the use of the South Kensington Museum on the 15th of May, for the purpose of holding the Society's Annual Conversazione.

Resolved—That the best thanks of this Council be given to the Offical Staff of the South Kensington Museum for the excellent arrangements for the Society's Conversazione on the 15th of May, and for the courteous and efficient manner in which they were carried out.

Sessional Address in October.

Mr. Stoddart, of Bristol, being requested, consented, to deliver the inaugural sessional address in October.

Finance Report.

The Report of Messrs. Haselden, Betty and Greenish, who acted as the Finance Committee in auditing the accounts for the past month, was presented, showing on the General Fund account a balance of £3685. 5*s.* 8*d.*, and submitting for payment accounts amounting to £989. 4*s.* 8*d.* On the Benevolent Fund account a balance of £670. 18*s.* 5*d.*

Resolved—That the Report be received and adopted, and payments made.

Resolved—That the Treasurer be requested to purchase Stock on the following accounts:—

General Fund...... New Three per Cents. £1000
Benevolent Fund .. Consols £500

The Report of the Parliamentary Committee was received.

Resolved—That the Report and recommendations of the Library, Museum and Laboratory Committee be received and adopted, and that the following books be purchased for the Society's library:—

Pharmacopœia Germanica.
Buchner's Commentär zur Pharmacopœia Germanica.
Silver's Outlines of Elementary Botany.
Miller's Chemical Physics, 5th edition.
Davies' The Preparation and Mounting of Microscopic Objects.
Balfour's Class Book of Botany, 3rd edition.
Johnson's How Crops Grow, revised by Church and Dyer.
Latham's English Grammar.

Benevolent Fund.

Election of Annuitants.

Resolved—That it is expedient and desirable that notice be given in the Journal that this Council will be prepared to elect, in October next, two annuitants on the Benevolent Fund; each annuity of the value of £30.

REPORTS OF THE BOARDS OF EXAMINERS.

Scotland.

April, 1872.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	3	2	1
Minor	9	7	2
Modified	4	2	2

Minor	49	24	25
	54	26	28

Preliminary.—Certificates received:—

Law Society	1
College of Preceptors	3
University of Oxford	2
" Cambridge	1
	7

Mr. Schacht inquired whether candidates who passed the examination were entitled by virtue thereof and on paying the fees to assume the name of chemists and druggists and go into business without any inquiry as to whether they had had any experience in the trade?

The Secretary said the examiners were bound to examine all candidates who presented themselves irrespective of where or how they acquired their information.

Mr. Williams said that was the principle which the Society had always held, that they would not insist upon apprenticeship, but that provided candidates satisfied the examiners of their capacity to conduct a business, they were allowed to do so.

Mr. Betty then rose to move the resolution of which he had given notice:—

"That such reporters as the Council may decide to invite be allowed the opportunity of reporting the proceedings of the Council."

He said about three years ago the first motion for publishing the proceedings was given by Mr. Brady, of Newcastle, but at that time the idea seemed so utterly impracticable that it was not acted upon in any way. Last year, however, on his own motion for the admission of reporters, the stronghold of secretiveness fell down like the walls of Jericho at the trumpet blast. The gentlemen who had been previously contented to sit at the Council Board and conceal their opinions as far as their constituents were concerned, for that was what it amounted to then, so far conceded the point that it was decided that the proceedings should be published, but only in a certain manner. Being able no longer to contest the principle, they fell back on a way of defeating it to some extent, which consisted in filtering the reports so finely through the Publication Committee as to make some people, at all events, suppose—and they ought to avoid all suspicion of the sort—that they filtered the very essence out of the proceedings. Now, what was the nature of the resolution proposed at that time? It was that the proceedings should be submitted to a committee, consisting of the President, Vice-President, and one other member of the Council. He contended that this arrangement was undignified in every way, and not conducive to the best interests of the Society. He also believed that such a mode of proceeding encouraged the diffusiveness which occupied a great deal of time, and detracted from the efficiency of their labours. If gentlemen who spoke at the Council were persuaded that they were speaking *coram populo*, and that what they said here would be attributed to them outside, they would not be as often led away from the business in hand, and the work would be much better done. In addition to this, he took it to be an impossibility that any one who took an active part in a debate could be a proper person to judge of the feelings, sentiments and impressions of those who had been opposed to him. It was a psychological impossibility for the President, for instance, to fairly appreciate those arguments which did not commend themselves to his own mind, and, therefore, it could not be expected that he would fully represent the spirit of any such remarks. It was not the right thing that any one should control the reporting of the debates who was deeply interested in the proceedings, and who might take a leading position with regard to any question at issue For these reasons he thought it not desirable that they should continue with their present imperfect system of reporting. He was not unaware of the fact as a member of one year's standing on the Council that there were practical difficulties in the way, and he was not bringing forward this resolution with the intention of catching a division or of in any way hampering their proceedings; but he looked upon this Council as something more than a debating society, and he did not wish the question to be argued on matters of detail, but simply on abstract grounds. He had seen the difficulties and dangers to which they were exposed; and he was most anxious in bringing this matter forward that, whilst affirming the principle that being a representative and administrative and deliberating body they ought to be fully reported to those whom they represented, still he wished that every safeguard which the Council might deem necessary should be interposed to prevent any inconvenience arising. He was aware that a great distinction must be made between public and private business. In order that the matter should be decided upon principle and not on mere matters of detail, he would propose that the matters to be reported should be only of a public character; and, moreover, in order that the manner of carrying that out should be such as was most in the interests of the Society, he would move that a committee be appointed to report to the Council as to the best mode of carrying out the principle he desired to affirm. He did not wish the Council to be led into the slightest personal inconvenience, and was aware that these matters required great caution. If the Council thought that with these safeguards which he had enumerated, the principle should be affirmed that matters to be reported should be simply matters of public interest and not private, and that a committee should be appointed to decide as to the best form of carrying out the resolution, he thought every practical difficulty would be obviated, and he desired this motion should be decided upon principle. Before sitting down, as he felt very strongly upon this matter, he would urge upon every member not to be afraid of their own shadows, but to have the courage to let whatever opinions they expressed be published in the Press the next day.

The PRESIDENT said Mr. Betty seemed rather to have departed from the words of his resolution, inasmuch as he now proposed the appointment of a committee.

Mr. BETTY said he should stick to the words of his resolution, but in order that the debate should not take place upon matters of detail, he added that if the principle were affirmed, he would propose the appointment of a committee to carry it out.

Mr. BROWN suggested that the resolution should be modified, and stand thus:—

> "That it is desirable that such reporter, or reporters, as the Council may desire to invite be allowed the opportunity of reporting the proceedings."

Mr. BETTY said perhaps that would be the more convenient way of doing it, and he would accept the suggestion.

Mr. WILLIAMS said he could go with Mr. Betty this length, that the reports should be published more fully than they had been, but did Mr. Betty wish to have other reporters admitted? and if so, how many, and how would he have any control over such other reports?

Mr. BETTY said the Council would invite such reporters as they thought fit.

Mr. HAMPSON said he would second the resolution with great pleasure. For a considerable time he had felt that the proceedings of the Council were not reported satisfactorily either to themselves or to the members at large. Opinions were expressed at the Board of really vital importance, affecting the trade at large; and he thought the trade had a right to know what members representing them said upon the subjects under discussion. However anxious the two or three individuals might be who, as Mr. Betty termed it, had to filter the report, to do so fairly it was utterly impossible for them if they took any interest in the question under discussion, to give a fair and honest report. But it was of great importance that matters which took place from month to month should be ventilated immediately and not allowed to accumulate, but that the opinions of those outside should be expressed upon them as they arose throughout the country, and they could then be much better decided. A man might not be able to express himself in fine language, and would not be reported at length, but half-a-dozen words would really give the pith of his argument, and this might have an effect upon other minds, whereas if it was simply stated that he seconded a resolution, or voted for this or that, it was impossible for the members outside to know anything about what his opinions were. This he believed was one great cause of those extraneous organizations of which they had heard, and which some gentlemen had such an objection to. He did not think there was a gentlemen present who really objected to the principle involved, although it was a new thing, and many new things were unpleasant, still, under the Pharmacy Act, they now had to make regulations as to matters which affected the whole trade, and they were bound to give the members at large the full benefit of their deliberations.

Mr. SANDFORD said he was one who certainly was of the contrary opinion on this point. Mr. Betty had talked a great deal about filtering the reports; but he could tell him there had been no filtering of an objectionable kind, and if Mr. Betty had read through the shorthand-writer's notes from the beginning of the year to the end, he was quite certain he would have filtered them as extensively as had been done. He (Mr. Sandford) had had a great deal to do with this matter, and he felt that the reporting had been done honestly, and that there had been nothing suppressed which any one gentleman present would say ought to have been inserted. When it was said that it was impossible for the President, who would take one view, to fairly represent the views of a gentleman who took the opposite side, it was forgotten that it was quite possible that another gentleman on the Committee might hold the opposite view; and therefore both sides would be fully represented. Gentlemen who had been sitting on the Council even for one year must know that there was an immense amount even of what might be called public business which was not suitable for publication. There were many matters coming up affecting different individuals which it would be most injurious to publish, at any rate when they were first mentioned. Therefore, there were many matters of really public business which must be carefully and only partially reported; but he would move, as an amendment,

> "That a Committee be appointed to consider the advisability of admitting other reporters to the meetings of this Council, and that the shorthand-writer's notes of the past year be put into the hands of the Committee, in order that it may be seen whether any matter which it would have been desirable to publish has been suppressed."

He felt that any Committee, looking over those notes, would feel as the President and Vice-President and he had felt,—that they had reported everything which ought to be reported. Other members of the Council had been present on several occasions,—for instance, Mr. Bottle and Mr. Mackay,—and they would be able to say that there-was no desire to suppress anything which ought to be published. The reports of the last two meetings of the old Council were said to be more full than they ever had been before; but the fact was that the subjects were more particularly interesting to the country, and could therefore be published with advantage, and also their reporter had, he thought, given them better reports of late, which he explained in this way,—that coming amongst them twelve months ago a perfect stranger, he did not understand the proceedings so well as he did when he was better acquainted with them. Taking the sheets sent in by the reporter, it was now only necessary to draw a pencil through such parts as were not to be published, and leave the rest almost entirely unaltered. He therefore thought it would be much more satisfactory to appoint a Committee without affirming the principle now; because the matter must be looked in the face, and they must consider who they were going to invite. If reporters in general were admitted, they could not exclude one and admit another, and all papers connected with the trade, and perhaps the medical journals, might claim to send reporters, which he thought would be very inconvenient.

Mr. Williams said he would second the amendment in order that it might be discussed, because he thought the real question was whether they should have one reporter under their own control, or other reporters not under their own control, and he was certainly an advocate for having one reporter under the control of the Council. In his opinion it would be very objectionable to have strangers present whom they could not control in any way, or direct as to what should be published and what not.

Mr. Savage said he would much rather leave it to the gentlemen who were accustomed to report proceedings of public meetings. He had sufficient confidence in reporters to believe that they would not publish anything improper. There was of course a great deal said there which no one would like to see in print, but he believed that reporters would only give the matter which would be interesting to the members at large. He did not care about anything he said or did being reported, but one incident had occurred to him which illustrated the matter. He gave a notice of motion at the suggestion of others, to the effect that it was desirable to keep open the Library in the evening, and there was no notice whatever taken of that until the notice appeared in the Journal that the library was to be opened. Now he could see no objection whatever to have reported that the question was brought forward by Mr. Savage at such a time, and then those gentlemen who had communicated with him on the subject, would have known that he had brought it forward, whereas he had to write to them to tell them that it was under consideration. He felt sure that whether there were one or more reporters present, they would be quite safe in their hands, and a great deal of trouble would be saved to the Committee who now superintended the publication.

Mr. Owen supported the resolution, and said it would be quite competent to the Council to request the reporters to leave the room if any private matter were under discussion.

Mr. Urwick said he fully agreed with publicity himself, and was quite willing to trust to the reporters, who, he was sure, generally speaking, flattered most people in their reports. He should therefore support Mr. Betty, but with the understanding of a Committee being appointed, because he did see difficulties in the way.

Mr. Stoddart said there were matters occasionally coming up which members would have difficulty in speaking upon if they thought they would be reported the next day, and many instances would occur to the minds of gentlemen present of questions which were discussed, and which ought to be discussed, but which it would not be pleasant to see published. But, if these difficulties could be obviated, he saw no objection to reporters being present.

Mr. Schacht hoped Mr. Sandford would not press his amendment, for it would be a very invidious and unpleasant task if any committee, such as he proposed, were to be appointed to have to go through all the shorthand writer's notes of the past year and report whether the Publication Committee had done their duties honestly and fairly. Speaking, however, on the abstract principle, as far as he understood the matter, he thought there ought to be the fullest possible publication of their proceedings, and he could not help thinking that in any public business the more gentlemen were aware that whatever they said would be reported, the more careful they would be as to what they said and their deliberations would be conducted with more dignity, and perhaps with better judgment. There would, no doubt, be a difficulty here and there, but he had expected to hear much more on that point than he had. The only point of much consequence appeared to be that occasionally questions arose touching individuals in the trade which would naturally not be laid before the whole world; but all such personal questions might surely be discussed beforehand in committee, and they would not be broached in the Council room until the matter had been completely sifted and verified. He certainly hoped that Mr. Betty's motion would be carried unanimously, and thought they would then find that the Council and its constituents generally would be at one.

Mr. Baynes thought the reporting might be safely left in the hands of the reporters who were, as far as his experience extended, free from any political or other bias, and were thus able to report any matter which came before them freely, fairly and impartially. But he must say that in years gone by, when he had taken part in public proceedings, he had gone home somewhat nervous as to what he had said, and had been quite rejoiced the next morning on reading the report. He was quite sure, therefore, that those gentlemen would exercise a reasonable discretion, and that no one need fear anything being improperly published. With all respect to the gentlemen who had acted as the Publication Committee, he thought it must be a most unpleasant duty for them to supervise the speeches of gentlemen from whom they might materially differ, and would be exceedingly difficult for them in such a case to give the whole force and effect of what was meant by the speaker. A reporter having no feelings whatever on the matter would see very much clearer what the speaker was aiming at, and if he was obliged to report only one fourth of what was said, he would make the speech a much better one in reading than it was when delivered.

Mr. Sandford said, in order to meet Mr. Schacht's objection, he would omit the last words of his amendment respecting the reporter's notes, and substitute for them the following words: "*in order to assist them* (*the Committee*) *in the consideration of the matter.*" He really wished they would look through the reports, because there was a sort of charge against the Committee of having suppressed matters. It was said that they had not reported fully, but it was a most remarkable circumstance that during eleven months of the year there was not a member of the Council who ever said that the report was insufficient. He challenged them all on that point. With regard to the instance mentioned by Mr. Savage, he did not know that it was ever usual to report notices of motion until they were brought on for discussion.

Mr. Sutton said Mr. Schacht had nearly expressed his views on the matter, but he should like to put forward a second amendment to the effect:—

> "That the reporter now engaged to take shorthand notes at the Council Meetings be required to take full reports of the proceedings of Council, and that the same be published in the Journal, except in so far as may be otherwise ordered by the Council."

Mr. Brown said he should vote for Mr. Betty's motion, and he did not see that there was any occasion for Mr. Sandford's amendment, because the motion was that such reporters as the Council should decide to invite should be admitted, and the Council might, and he thought very probably would, decide that they would only invite one reporter, the same as at present. He did not think it at all desirable that any reporters who might apply should be present, and thought it more than likely that as heretofore the Council would decide to invite only one. He did not think there was any risk of private matters being reported in an undesirable form, because he believed that when it was known that the proceedings of the Council were more fully reported, and that the shorthand writer exercised simply his own discretion, subject to the supervision of the Editor of the Journal, the proceedings would be very materially shortened, and another advantage would be secured that the committees would do their work much better than they did at present. During the last two years he had certainly seen a great deal of work done at the Council Board which ought to have been done in committee, the results only being submitted for confirmation. There was another means of getting rid of any difficulty with regard to personal matters which always would be coming up for discussion, and that was to refer them to the General Purposes Committee, which could be summoned for any time, and which consisted of all the members of the Council. In this way any subject which it was not desirable to discuss in public could be ventilated and afterwards brought before the Council in such form that there could be no danger of any one's feelings being hurt by the proceedings being published. He could see no practical inconvenience from the adoption of the motion, and in justice to the members of the Council themselves, and certainly in justice to the whole of their constituency who earnestly desired that this change should take place, he should vote for it; but in doing so, he must say that he did it with the reservations that from his own personal knowledge, he could acquit the gentlemen who superintended the publication from any charge of improperly filtering the reports submitted to them. He had been surprised at the amount of pains and trouble taken; and whatever had been suppressed had been done in charity to the readers and from the very best motives, and certainly with the purest intentions.

Mr. Sandford said after what Mr. Brown had said he would withdraw his amendment, but it certainly put a new complexion upon the motion. He understood Mr. Betty desired the Council to affirm the principle that other reporters should be admitted, whereas Mr. Brown said he did not accept that interpretation.

Mr. Hills said he had objected previously to the admission of reporters altogether, but the time for that had passed by, and he would now support the motion if Mr. Betty would confine it to one reporter. He was quite content for their own reporter to make his reports as full as he chose and, if he liked, to supply them to other journals. He was therefore quite prepared to support Mr. Betty after Mr. Brown's explanation—at any rate, that they should only have one reporter to begin with.

Mr. Sandford said if they were not now affirming the principle that other reporters should be admitted, he would vote with Mr. Betty.

Mr. Betty said the principle he wanted to affirm was that they should not make speeches and then dress them up themselves for publication afterwards, but that every expression of their sentiments and their policy should be published through the legitimate channel. He believed that in every other institution which published its proceedings, it was done through the medium of gentlemen of the press, who understood their business much better than any amateur triumvirate could do. It might perhaps at first sight be more agreeable to the feelings of some members to know that nothing they said should appear unless it had the sanction of one or two of their fellow-members, but they were quite as likely to err as a reporter, whose business it was to attend to such matters. He should leave it to the committee to decide who should be admitted. He only desired to affirm the principle and leave them quite untrammelled. He did not wish to bind them to admit two reporters, nor on the other hand, would he admit that it would be always desirable to confine it to but one. It was a matter of detail which he would leave to the Committee.

Mr. Sandford said he would withdraw his amendment if the understanding was that the motion did not pledge them to admit other reporters, but if it did he must press the amendment.

Mr. Betty said he could not ask for Mr. Sandford's vote under the slightest misapprehension as to his meaning. It was entirely a matter of principle whether their proceedings should be made public or not, and he was not to be bound down or hampered in the wording of the resolution as to how it should be done. He wanted to affirm the principle that there should be general reporting and full reporting.

Mr. Sandford said there might be the fullest reporting with their own reporter.

Mr. Betty said it would be open for the committee to appoint one reporter, but he would not bind them to do so, nor in any way prejudge the questions submitted to them.

Mr. Brown said he must not be misunderstood. He most entirely agreed with the principle that it was desirable that the proceedings should be fully reported, but he thought it more than probable that when the committee came to deliberate on this subject, they would consider it desirable, at any rate for the first twelve months, to have only one reporter. This was a great and radical change, and they must have time to get accustomed to it.

Mr. Sandford said he would withdraw his amendment, because the discussion would stand on record, and would show in what way the motion was voted for and carried, and that they were not pledging themselves to the admission of other reporters.

The President said that there was still Mr. Sutton's amendment; but, before putting it, he would say a word or two, having had a good deal to do with the publication of the proceedings. If anything had been kept back, it was not from any desire on his part. No doubt many would remember that on more than one occasion, when a particular question had been brought forward, he had asked the Council whether the discussion should be reported or not, and the answer had been in the negative. Sometimes, again, he had asked gentlemen, after the Council, whether they would like their remarks reported in full, and they had replied, "Not exactly." For himself, he had no objection to publishing every word that was spoken, and he thought they might be published from the notes of their own reporter quite as well as from any others. The only objection he saw to the motion was that the word "reporters" was used in the plural. He thought one reporter sufficient, and that he should be the one engaged by the Council; he could see no advantage in having two or three reporters. With regard to the circumstance referred to by Mr. Savage, he believed the regulation as to opening the library in the evening was published in the Journal as soon as possible; and it was not customary or desirable to publish notices of motion, which might, from various circumstances, be withdrawn and not discussed or acted upon.

Mr. Sutton said he must press his amendment, because he thought the principle to be decided upon really was, whether one reporter or more should be present. He thought there should be one only, but that no restriction should be put upon his discretion in reporting the proceedings.

The President said the only difference seemed to be as to the use of the plural "reporters." Perhaps Mr. Betty would alter his motion so as to meet Mr. Sutton's view.

Mr. BETTY said he could not do that. The question really was whether the publication of the proceedings should be under the control of the Council, which he contended was a vicious system, or whether it should be left in the hands of the press, whose impartiality no one would dare to impugn.

The PRESIDENT thought one reporter was as good as half-a-dozen.

Mr. BETTY said it was no use appointing a Committee and tying their hands.

The PRESIDENT said he would put the amendment, Mr. Sutton having altered the wording so as to avoid the necessity of a needlessly diffuse report being published.

Mr. SANDFORD said the right of control must be reserved to the Council. They must be masters of their own proceedings.

Mr. BROWN: Are the proceedings of this Council public or private?

Mr. BETTY said he thought they were public, or they could not be published.

Mr. SANDFORD said, in his opinion, they were private. It was quite competent for any one to publish private proceedings if they liked.

Mr. SCHACHT did not apprehend that the proceedings of any representative body could be private.

Mr. BROWN said that this was a question which every member ought to settle for himself. He had always regarded them as public. He considered the mere fact of allowing any report to be published, militated against the contention that they were private proceedings. He thought every member ought to be prepared to stand or fall by his utterances. If there were any matter advisable not to be published, they could resolve themselves into committee.

The amendment was then put and lost, and the original motion, as altered by Mr. Brown, was put as a substantive motion and carried.

It was then moved by Mr. BETTY; seconded by Mr. BAYNES, and Resolved—

"That a Committee be appointed to inquire into and report to the Council the best means of carrying into practice the vote of the Council for the admission of a reporter or reporters, and that the following be the Committee:—Messrs. Betty, Bottle, Hampson, Mackay, Sandford, Savage, Sutton, Urwick and Williams."

Mr. BOTTLE said he was present on one occasion when the Publication Committee were at work, and he was bound to say that he could fully bear out all that had been said as to the work being done most honestly and laboriously; and he was certain the Committee desired to publish not only their own views, but the views of those opposed to them, and he moved,

"That the President, Vice-President, and Mr. Sandford be appointed a Committee, *pro tem.*, to superintend the publication of the proceedings of the present Council."

This was seconded by Mr. SAVAGE, and carried unanimously.

Mr. BROWN said he would now move in accordance with the promise he had made at the General Meeting,

"That the solicitor of the Society be requested to draft and submit to the next meeting such an alteration in the bye-laws as will provide that due notice should be given of any proposal for the Annual Meeting by which the legal position of Members of the Pharmaceutical Society, or of the general body of chemists and druggists, would be altered."

He thought this would be the better way of dealing with the question, because if he suggested the terms of the new bye-law, it would have to be referred to the solicitor afterwards, and the course he proposed would save time.

Mr. SCHACHT seconded the motion.

Mr. WILLIAMS said the first question was, did they desire to make any alteration in the bye-laws, which was a very serious matter? Such a bye-law as was proposed would really give the chairman of an Annual Meeting power to stop the business, and he thought it involved a dangerous principle.

Mr. SANDFORD thought the resolution, in principle, a good one, and Mr. Flux had stated that there would be no difficulty in framing a bye-law to the effect that no motion which would involve legal consequences under Section I. of the Act, should be brought forward without due notice.

Mr. BROWN said it was only under Section I. that any legal consequences could arise. He considered that it would be an insult to the Council, who were chosen to conduct the affairs of the Society, for any member to bring forward an important motion at a general meeting without first laying it before the Council.

Mr. HAMPSON thought they were bound to make the alteration in the bye-laws if possible. It was one which would cut both ways, and he could not see any possible objection to it.

Mr. URWICK said he should support the motion, for he had been quite astonished at the last meeting to find they were in such a state as to require it, which he did not think was the case with any other similarly constituted body. He was in favour of the right to a poll in case of dispute.

The PRESIDENT said no doubt the solicitor would inform them that he could frame a bye-law, but that it was not usual for a Society to tie its own hands more than necessary.

Mr. BOTTLE thought such a bye-law as was proposed was contrary to the spirit of the Act of Parliament.

Mr. BETTY said the bye-law would not override the Act of Parliament, it would simply prescribe the mode in which the action contemplated in the Act should be carried out.

The resolution was then put and carried.

The SECRETARY read a letter from Mr. Sowerby, Secretary to the Royal Botanical Society, stating that the same facilities would be given to students attending Professor Bentley's class as heretofore under the same regulations.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The thirteenth General Meeting was held May 9th; the President, Mr. E. DAVIES, F.C.S., in the chair.

The PRESIDENT showed one of Fletcher's gas furnaces, and made some trials with it to show its efficiency.

Mr. A. E. TANNER described the process of making perchloride of iron with chlorate of potassa, and said he found that it gave very satisfactory results.

No paper was read.

The fourteenth General Meeting was held May 23rd; the President, Mr. E. DAVIES, F.C.S., in the chair.

The HON. SECRETARY referred to the paper which had been read before a meeting of the Pharmaceutical Society in London by Dr. Redwood, on the "Substitution of Proportional Numbers for specified Weights and Measures in the description of Processes in the Pharmacopœia," and which was published in the PHARMACEUTICAL JOURNAL of Dec. 9th, last year, and said he felt sorry that the subject had not been brought before this association, as Dr. Redwood had stated that his object was to receive the opinion of practical men as to the desirability of carrying out the proposed change, before he devoted the time and labour necessary to recast the formulæ, and he thought the best reply would be the expressed opinion of the different associations throughout the country. He hoped the subject would be fully discussed next session. His own opinion was that if the proposed change would lead to an earlier adoption of the metrical system, it should be adopted; but its value and utility was principally as a means to this end.

The PRESIDENT said he should like to see the metrical system adopted at once. It had been introduced into almost every continental country and some in South America, and he trusted the time was not far distant when it would be also introduced and universally applied in England.

The PRESIDENT then read the following (the valedictory address of the session):—

"In the absence of any recognized formula for the production of valedictory addresses, I may be excused if I bring rather a miscellaneous assemblage of subjects before you this evening. The range of interesting matter embraced by the objects of the Chemists' Association is so wide that many points must go untouched; and if I fail to mention any facts new to all, or to give any new or valuable views of my own on vexed questions, I hope to excite some little discussion, or to suggest some lines of thought which the members may develope for our mutual profit.

"No startling novelties have marked the record of chemical discovery since I addressed you at the opening of the session. In the field of artificial production of organic compounds,—one of the most important now worked by chemists,—the only one with which I have met is the formation of dulcite,—$C_6H_{14}O_6$,—a substance resembling mannite, obtained from *Melampyrum nemorosum* and other sources—by hydrogenating galactose, a product of the action of dilute acids on milk sugar. This was naturally suggested by the previous artificial production of mannite from glucose. I refrain from speaking of the numerous researches in organic chemistry which have been recently made, as many of them are of purely scientific and limited interest. Some, having a special reference to the properties or composition of drugs, I will now bring before you.

"Opium, which is about the most heterogeneous mass of organic bodies, has had its complexity still further developed by the addition to the list of cryptopine, protopine, laudanosine, laudanine, codamine, and hydrocotarnine. Dr. Wright is still working on the opium alkaloids, with results which promise valuable information as to the constitution of these bodies. An improvement in the iodic acid test for morphia increases the delicacy of this reaction, so as to render the detection of that alkaloid much more certain.

"Senna is a still more difficult body; and here I regret that we seem further off than ever from a clear insight into the active principle or principles of the leaf. The main results appear to be that there are several purgative substances in this drug,—chrysophanic acid, cathartic acid, and some other not determined; the cathartine of Lassaigne and Feneulle being shown to be a mixture. (Bourgoin and Bouchut.)

"Therapeutics are perhaps scarcely admissible; but anything like an intelligible idea of the action of medicines is so rarely to be met with, that no excuse is needful for bringing before your notice an investigation on the influence of quinine on oxidation in the blood (A. Schulte). In this, quinine is shown to arrest fermentation and putrefaction, killing fungi, bacteria, etc., and stopping the action of certain substances which produce ozone. The red corpuscles of the blood can do this, and therefore quinine diminishes oxidation, lowers the temperature, and arrests fever. Naturally, waste of tissue also diminishes; and a very remarkable fact is that picrate of sodium will act in the same way, whilst cinchonine has much less influence.

"I think that in my opening address I made a very fair prophecy as to the utter futility of our present laws for preventing, or rather punishing adulteration; and I appeal to the experience of the tentative efforts of the Corporation as a fulfilment of it. With regard to adulteration, Englishmen will do anything but act. They will write to the papers, conjure up the most horrible pictures (mostly false) of the practices of the unprincipled adulterator, will assure you that they know that the food they buy is not genuine; and yet they will not walk to the end of the street to have an article tested. Our papers, big and little, carefully informed the public that they could have any article of food analysed for nothing, that no personal appearance in any prosecution would be needed, no risk run of being a martyr for the public good, and that the trouble and expense would all fall on the broad shoulders of the Corporation. Yet where is the result? I have looked daily in the papers for any action, but in vain, and I can only draw two conclusions. One is, that every fraudulent sinner in Liverpool has seen the error of his ways, has destroyed his adulterated stock, and told the wholesale dealer that henceforth nothing but pure articles, at a fair price, will be received,—a moral revolution of which we might well be proud, even though fear of the public analyst had supplied the place of conscience. But I fear that this is too fair a picture, and that the truth is, firstly, laxity on the part of the public; and, secondly, a well-grounded despair in the official mind of doing anything in the present state of the law.

"While on this subject, I have much pleasure in calling your attention to a series of papers in the PHARMACEUTICAL JOURNAL by Mr. Pocklington, on the use of the microscope in the detection of adulteration and the study of the minute structure of drugs.

"I would willingly abstain from any allusion to the question of help to schools of pharmacy from the central body, but it has assumed sufficient importance to demand some remarks. Of course I speak for myself only, and my double position as President and Teacher must make me careful. We may lay down a few axioms which may assist our thought on this matter.

"1. Education of a special kind must be provided for young men if they are to pass the examinations. This education is not generally to be met with in educational establishments. Chemistry is certainly pretty universally receiving attention, and in almost all large towns some measure of instruction is available, but as to botany, pharmacy and materia medica, teaching must be specially provided.

"2. Many masters are themselves unable, even if willing, to give such instruction to their apprentices.

"3. Pecuniary and moral reasons prevent many parents from sending their sons to London.

"4. Even if large numbers join classes, the fees, which must not be large, will not give adequate remuneration to teachers. The cause is not one which appeals very forcibly to public sympathy, important as it is, and there is no very direct interest to draw support from those already in business.

"5. The establishment of schools in small places is impossible from lack of means and teachers.

"From these data I draw the conclusion that central places judiciously selected over the country, will afford the only way of establishing schools of pharmacy with any chance of success. With regard to funds three sources present themselves, students' fees, public money, and help from the Pharmaceutical Society. The first on all hands is admitted to be insufficient; Mr. Lowe will demur to the second, and the last remains as the only resort. Local effort should supply a place and fit it up, and then one teacher competent to instruct in all the subjects required should have a minimum amount secured, and after that receive payment on results. Members in small places cannot complain, for at present they have no means of instruction, and this plan would bring it nearer their doors.

"Doubtless there is great indifference on the part of those who have to pass the examinations, or else they are not afforded time. Six for a course of chemistry lectures, two for practical chemistry, and seven for lectures on botany are not very encouraging figures, but we must remember that desultory efforts are rarely successful.

"Our session has not been quite as successful as I would have wished. I have from various causes been unable to do all that I wished and intended when I undertook the office of your President, and must hold myself responsible for some part of the lack of interest manifested. Still papers of considerable value have been read; and on the evenings when papers have been provided, the attendance had been good. I can only express a wish that during the summer you may lay up, like bees, some honey for next winter.

"Dr. Carter has begun a course of lectures on botany, in the arrangements for which he showed the utmost liberality. Members may still join without losing much, as practically only one lecture has been delivered. The minimum number has not been quite reached, and, therefore, the course is yet in danger; but I hope that this will not continue. Though I fortunately have no Minor or Major in view, from the love I have for botany, I have enrolled myself among the doctor's pupils, and anticipate much pleasure and profit. And now I must say farewell, with thanks for your kind consideration during my presidency. May we all remember that knowledge for the love of it should be our motive power, and then with open eyes, in the shop or study, in the crowded street or country lane, we shall not lack objects for profitable consideration to make us wise and better men."

A vote of thanks to the President for his address and for his labours during the session, and also to the Honorary Secretary for his services, terminated the proceedings.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Annual Meeting of the above Society was held on Tuesday, May 28th, when the following officers were elected for the ensuing year:—

President, Alderman W. Thompson; *Treasurer*, Mr. R. Robinson; *Secretary*, Mr. J. J. Nicholson. *Council*, Messrs. J. Harrison, D. B. Sharp, H. Thompson, T. Nasbet, C. S. Lord, J. Mitchinson, H. Turnbull, T. Burn, and J. Priestly.

The Secretary and Treasurer's reports were read and adopted.

Among other resolutions adopted was one proposed by Mr. J. Harrison and seconded by Mr. Hodgson, that a petition be forwarded to the House of Commons in favour of the Bill for exempting chemists and druggists from service on juries.

It was announced by the Secretary that arrangements were in progress for a series of lectures during the next session; and after cordial votes of thanks to the retiring officers the meeting separated.

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

Friday, May 31.

The following Bill was, on the motion of the Earl of Morley, read a second time and referred to a Select Committee:—

A Bill to Amend the Petroleum Act, 1871.

Whereas by Section 3 of the Petroleum Act, 1871, it is enacted as follows:—"For the purposes of this Act the term 'Petroleum' includes any rock oil, Rangoon oil, Burmah oil, oil made from petroleum, coal, schist, shale, peat, or other bituminous substance, and any products of petroleum, or any of the above-mentioned oils; and the term 'Petroleum' to which this Act 'applies,' means such of the petroleum so defined as, when tested in manner set forth in Schedule 1 to this Act, gives off an inflammable vapour at a temperature of less than one hundred degrees of Fahrenheit's thermometer;" and it is expedient to substitute the test in the schedule to this Act for the test in Schedule 1 to the Petroleum Act, 1871:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. The schedule to this Act shall be substituted for and be deemed to be Schedule 1 to the Petroleum Act, 1871, and "85" shall be substituted for "100" in Section 3 of the same Act; and the Petroleum Act, 1871, shall be construed accordingly.

2. The Petroleum Act, 1871, as amended by this Act, shall be perpetual.

3. This Act may be cited as the Petroleum Act, 1872, and this Act and the Petroleum Act, 1871, may be cited together as the Petroleum Acts, 1871 and 1872.

4. Section 18 and Schedule 1 of the Petroleum Act, 1871, are hereby repealed, provided that this repeal shall not affect:

(*a*). Anything duly done or suffered before the passing of this Act under the Petroleum Act, 1871; or

(*b*). Any penalty, forfeiture, or punishment incurred in respect of any offence committed before the passing of this Act against the Petroleum Act, 1871; or

(*c*). Any investigation or legal proceeding in respect of such penalty, forfeiture, or punishment, and any such investigation or legal proceeding may be carried on as if this Act had not passed.

5. This Act shall not come into operation before October, 1st, 1872.

Schedule.

Directions for testing Petroleum to ascertain the Temperature at which it gives off Inflammable Vapour.

The apparatus to be employed in this test shall consist of—

(*a*). An outer vessel of metal to contain water, about four inches in diameter and four inches deep, so contrived that some source of heat, such as a spirit lamp or gas burner, can be applied to it to heat the water which it contains:

(*b*). An inner vessel of thin metal to contain the petroleum to be tested, about two inches in diameter and two inches deep, provided with an external rim or flange, above which the edge of the vessel shall rise about one-fourth of an inch, and by which it may be supported in the outer vessel so that its contents may be heated through the medium of the water.

The inner vessel for the petroleum shall be provided with a cover of thin metal fitting to the edge which rises above the rim or flange already described. This cover shall be about half an inch deep, so that its top may be half an inch above the surface of the petroleum to be tested. In the cover there must be fitted a Fahrenheit thermometer with a spherical bulb, in the scale of which ten degrees shall occupy at least half an inch in length; the thermometer must be placed in such a position that the bulb shall be just covered by the petroleum.

Near the front edge of the cover there shall be a circular opening, and through this the petroleum is to be tested. This opening is to be provided with a small movable cover.

In making the experiment with this apparatus the water in the outer vessel shall in every case be heated to eighty degrees Fahrenheit before the petroleum is put into the inner vessel. When the temperature of the water has reached eighty degrees, the source of heat must be withdrawn; the inner vessel must then be filled with the petroleum to be tested up to the level of the outer rim or flange, which must be indicated by a mark on the inside, and the cover with the thermometer must be put in its place. The source of heat must now be again placed beneath the vessel containing the water, and when the temperature of the petroleum in the inner vessel has reached eighty degrees, a small light should be applied to the circular opening in the cover; if the vapour be not ignited—that is, if no pale blue flash or flicker of light be produced—the application of the light should be repeated at about every two degrees of increase of temperature until the flash of the ignited vapour be observed, and the temperature at which the first flash takes place is the temperature at which that sample of petroleum gives off an inflammable vapour.

In every case a second experiment shall be made to check the results obtained in the first.

A model of the apparatus described above is deposited with the Warden of the Standards, and reference shall be made to it in case of any difficulty or dispute as to the meaning of the terms employed in this description.

HOUSE OF COMMONS.

Thursday, May 30th.

The Public Health Bill.

Sir C. Adderley asked the First Lord of the Treasury whether the Public Health Bill, relating to a subject which the Government pressed on the diligent attention of a Commission three years ago, and had twice advised Her Majesty to recommend to Parliament for immediate legislation, and which was now being postponed to other Goverment measures, might not have a morning devoted to its consideration in Committee.

Mr. Gladstone: I can so far comfort the mind of my right hon. friend, with whom we are quite agreed as to the importance of this measure, as to assure him that it would be a mistake to suppose that the Public Health Bill is postponed to the other principal measures of the Government. That is by no means the case, and we are very anxious to arrive at the time when we may deal with the Public Health Bill in the same way as with other principal measures of the Ministry—by devoting to it the whole available time of the House, so far as that time is under our direction and control. We hope to-night to dispose finally of one of the chief Government measures. We shall then proceed with the Scotch Education Bill in the same manner as with the Ballot Bill—that is, by inviting the House to give to it the whole of its available time. In our opinion that is the best way of disposing of all these measures, and we should not confer any real advantage on the Public Health Bill by devoting to it a mere fragment of time. It is for the sake of getting forward with that Bill that we wish to get rid of the measures which at present obstruct its progress.

Monday, June 3rd.

Use of Ether in Ireland.

Colonel Knox asked the Chief Secretary for Ireland whether his attention had been called to the great increase of intoxication in the north-west of Ireland, caused by the use of ether and a mixture of naphtha and ether, sold by chemists and grocers, and whether he was prepared to take steps to put a stop to the abuse, and deter parties who turn their establishments into dram-shops.

The Marquis of Hartington said the attention of the Irish Government had not been called to that matter lately, but as long ago as 1868 its attention was directed to it by a presentment of the Grand Jury of the county Tyrone, forwarded by Mr. Justice George. The Government then made a full inquiry into the subject, and ascertained that the practice of using ether as a stimulant instead of ordinary spirits was confined to the north of Ireland, and principally to the counties of Tyrone and Londonderry, where ether was taken not as an addition to whiskey, or any other spirit, to strengthen it, but merely diluted with water as a stimulant instead of ordinary spirits. Thereupon the Irish Government communicated with the Board of Inland Revenue as to whether any measures should be taken for checking that practice. The Board of Inland Revenue reported that in the existing state of law they could not interfere. The subject appeared to have been further considered by the Government; but, looking to the fact that that practice was almost confined to the two counties he had named, and that ether was very largely used for medicinal and many other purposes, it was not then thought necessary to take any further step in the matter. At present an inquiry was, however, being conducted under the direction of the Irish Government into the alleged adulteration of whiskey in many parts of Ireland. As soon as the reports on that subject were received, they would be considered by the Government, who would also take the opportunity of considering the question to which the hon. and gallant member had referred.

Tuesday, June 4th.

The Juries Bill.

On the motion of the Attorney-General it was agreed that the Select Committee on the Juries Bill do consist of 17 members:—The Attorney-General, Mr. Lopes, the Attorney-General for Ireland, Mr. Raikes, Mr. James, Mr. Kennaway, Mr. Watkin Williams, Mr. W. H. Smith, Mr. Lawrence, Mr. Amphlett, Mr. Pease, Mr. Floyer, Mr. Denman, Sir M. H. Beach, Lord G. Cavendish, Mr. Straight and Sir Wilfred Lawson.

Suicide by Prussic Acid.

On Wednesday, June 5th, Mr. Langham held an inquiry respecting the death of George Mellow, aged about 38, for 20 years in the employment of the Apothecaries' Company, at their Hall, in Water Lane, Blackfriars. The mother of the deceased said that for some time he had been in a bad state of health, and complained of pains in his head, but she never heard him threaten to destroy himself. On Monday morning he left his home to go to his work, when he said he was very sick and ill. She did not see him alive afterwards. George Brown said that during the last fortnight he had been employed in repainting Apothecaries' Hall. On Monday, about ten o'clock, witness went to the jacket-room, and found deceased lying on his back. He called for assistance; and, thinking he was in a fit, they pulled him out into the fresh air. Finding he did not recover, he was removed to the retail department and a surgeon was sent for, but deceased expired a minute or so before his arrival. Witness found on the floor a blue glass bottle, containing prussic acid, from which deceased must have taken about two teaspoonfuls. Mr. Robert Halley said that he considered deceased had not been in his right mind for several months past. Dr. Halse, of New Bridge Street, Blackfriars, said that upon his arrival he found him dead. The body smelt strongly of prussic acid. The jury returned a verdict of temporary insanity.

Poisoning By Oxalic Acid Contained in Black Draughts.

On Thursday, May 30th, Mr. Humphreys held an inquest at the Lord Hood Tavern, Rich Street, Limehouse, into the circumstances attending the death of James Simmons, aged 38, a mariner. The evidence given, which was very lengthy, proved that the deceased returned to London from a coasting voyage, and took up his abode as usual in Jamaica Place, Limehouse, in company with another mariner named Seaman. After being ashore for two or three days the two men asked their landlady to procure them two black draughts, which she accordingly did, purchasing them at the shop of Dr. Trail, of Limehouse. The two men drank off their draughts, but immediately after doing so the deceased fell down insensible, and died shortly afterwards; while Seaman was seized with violent vomiting, and suffered very severely for some days. By order of the coroner, Dr. Nightingale made a *post mortem* examination of the body, and found the whole of the organs of the body quite healthy, with these exceptions—brain intensely congested, effusion of blood into the cavity of the chest and into the pericardium or bag of the heart. The above facts were elicited at the opening of the inquiry, which was adjourned until yesterday to enable Dr. Tidy, professor of chemistry and medical jurisprudence at the London Hospital, to make an analysis of the contents of the stomach. That gentleman accordingly analysed such contents, and detected the presence of oxalic acid, and he said that it was highly probable that the death of deceased was due to swallowing some of that poison. He also told the court that in the preparation of black draughts Epsom salts were used, which much resembled oxalic acid in appearance, and that the person who made up the draughts in question had possibly used the poison instead of the salts by mistake. Dr. Trail explained that the two draughts in question were the last of a stock he bought in November last from the former owner of the business. The jury consulted for half an hour, and eventually recorded an open verdict, thus leaving the matter in the hands of the police.—*Times.*

Attempted Suicide by White Precipitate.

At Stourbridge, on Friday, May 24th, Mary Kendrick, a prostitute, was charged with attempting to destroy her life by taking a quantity of precipitate powder. It appears that she had been drinking freely for two days previous, and went to the shop of Mr. Morris, chemist, and there purchased the powder, which she mixed up in some liquid and drank. Dr. Campbell was soon in attendance, and applied antidotes.

Mr. Y. Lewellyn, assistant to Mr. Morris, chemist, said the prisoner came to their shop, and asked for a pennyworth of precipitate powder to dress heads with. She asked for the strongest. He supplied her with it, and said the white was the strongest, and cautioned her, stating what it was, and labelled it "Poison."

Martha Kendrick, sister to prisoner, said that the prisoner had a quarrel with her mother, and said she would go and buy some poison and poison herself.

Prisoner, in defence, said she did not intend to poison herself; but had something the matter with her head, and, having had a quarrel at home, she took it. Was very sorry, and would not attempt to take her life again, if discharged.

She was committed to take her trial at the ensuing ssions.—*Stourbridge Observer.*

The following journals have been received:—The 'British Medical Journal,' June 1; the 'Medical Times and Gazette,' June 1; the 'Lancet,' June 1; the 'Medical Press and Circular,' June 1; 'Nature,' June 1; the 'Chemical News,' June 1; 'English Mechanic,' June 1; 'Gardeners' Chronicle,' June 1; the 'Grocer,' June 1; the 'Journal of the Society of Arts,' June 1; 'Grocery News,' June 1; 'British Journal of Dental Science' for June; the 'Milk Journal' for June; 'Longman's Notes on Books' for May 31; 'Florist and Pomologist for' June; 'Practitioner' for June; 'Educational Times' for June; 'Food, Water, and Air' for June; the 'Doctor' for June.

Soothing Syrups.

Sir,—You state in last week's Journal that "most if not quite all soothing syrups, cordials and elixirs sold for the benefit of infants under the most amiable titles, contain opium." We beg to deny that this is the case as regards Mrs. Johnson's Soothing Syrup, of which we are proprietors; and to state that it is an exception to the rule you lay down, "that the whole tribe of infantile soothers belong to the tribe of poisons," inasmuch as our preparation does not contain opium, or any of its preparations, or any narcotic whatever. Mrs. Johnson's Soothing Syrup is not "a deadly poison and one which needs the utmost care and skilled vigilance to rob it of its danger when infants are compelled to swallow it," as it is not a medicine to be taken inwardly, but is only to be rubbed on the gums; and we repeat, contains no narcotic whatever—nor would any harm issue should the bottleful be administered by the nurse in mistake.

Barclay and Sons.

Farringdon Street,
June 3rd, 1872.

[*** The fact that Messrs. Barclay's Soothing Syrup is not a medicine to be swallowed obviously places it outside the class of preparations referred to in our article.—Ed. Pharm. Journ.]

Pharmacy at Home and Abroad.

Sir,—In the 'Journal de Pharmacie et de Chimie' for this month, I observe an announcement that has caused me certain painful reflections and humiliating comparisons. It is as follows:—"At Lyons, on the 18th September, 1872, will be opened a medical congress. This congress will be scientific and professional; it will last nine days. It will be composed of foundation members and ordinary members. Foundation members shall be doctors of medicine, *pharmaciens* and diplomaed veterinary surgeons." The programme to be discussed is purely medical.

How long will it be before a similar announcement will be possible in this country? Echo answers "how long," and I cannot be more definite. It would be safe, however, to venture a prediction that that day will not be hastened by the universal prevalence of the cheap and inefficient pharmaceutical education with which we are threatened, it seems, by the new Council.

Gamma.

May 31st, 1872.

W. Botham.—We have received the sample of your india-rubber valve for feeding-bottles, but are unable to publish any account of it except in the advertising columns.

F. Tebbutt sends a caution to the trade against the dishonest practices of two men, who have succeeded in some cases in robbing pharmacists. The plan they adopt is for one to withdraw the attention of the shopman to a pretended prescription, while the other perpetrates the theft.

J. H. Bland is thanked for his enclosure.

W. Bartlett is thanked for the information, which will be kept as a memorandum for future use.

J. Houlton has sent us a communication expressing his individual agreement with the statement in the advertisement of Winslow's syrup, that it is a real blessing to mothers and children, and giving some details of the quantity of that preparation sold by him. We are unable to see how this affects the argument of the editorial article of last week, which pointed out the advisability that such preparations should be so labelled as to indicate the necessity for using them with caution.

Communications, Letters, etc., have been received from Mr. J. Burt, Dr. F. Porter Smith, Mr. T. Stokoe, Mr. E. W. Howe, Mr. J. E. Lord, Mr. J. Wright, Mr. J. Thornton, Mr. J. Martin, Messrs. Kay Bros., Mr. C. R. C. Tichborne, W. F. C., R. J. M., "One who has Known," etc., "Tyro," "Photo," S. N.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p. 921.*)

JALAPA.—Tubercule or tuber of *Exogonium* (*Ipomœa*) *purga*. The general character of the tuber is sufficiently unlike the structure of the ordinary 'root' to make its inclusion here somewhat a digression, for which perhaps my readers will be thankful, as a relief from general tedium; the more so, as they will be saved from the technical description needful with many roots and the like. With the general characters of the jalap tuber, its appearance, colour, weight, and resinous fracture all pharmacists are familiar. These characters are all the concomitants of certain microscopic characters. The dark brown, almost black, colour of the exterior is confined to the cells of the layer immediately below the true epidermis. The cells of the epidermis are oblong in shape, much compressed, that is, *thin*, and have their front walls much thickened. The cells which contain the dark resinous colouring matter lie immediately below this, and are rounder in outline. Very considerable care and patience is needed to render these details visible in the dry tuber; in the form of powder they cannot be recognized at all; a few pieces of brown structure are all then discernible. The structure of the interior of the tuber is more characteristic, and may be described as being composed of a series of lamellæ, each of which consists in the middle of irregularly shaped cells with varying contents, and, on the exteriors, of more regularly shaped, more compressed parenchyma cells and vascular vessels, with exceedingly little pleurenchymatous and parenchymatous tissue. Some of the cells of this act as resin receptacula, others contain starch, and a few are nearly empty of all except the usual protoplasmic matter. The starch-bearing cells are irregularly hexagonal in shape, cell walls are thin and imperforate. The starch granules are large, vary much in size and shape, and lie loosely in the cells. They may be classed as aggregated and isolated granules. The aggregated granules usually consist of three triangular granules, the bases of the triangles being curved outwards, so that the resulting granule is muller-shaped, but approaching the circular. Many of the isolated granules are nearly circular, flattened, with a triradiate, indistinct hilum. These give a very distinct black cross by polarized light, the intersection of the arms of the cross lying on the hilum point. In the aggregated granules the cross is not so easily visible, as the hilum then lies towards the centre of the aggregation, and some care is needful to get out the cross by careful rotation of the upper and lower prisms as may be required. Taking the starch altogether, it will be found to be highly characteristic.

The resin cells are less regularly shaped than those which contain starch. The resinous contents are somewhat granular, usually dark in colour, and partially soluble in water, which consequently renders the mass more transparent. Vascular ducts are not numerous, and consist of large 'barred' vessels, often perforate in the older laminæ. The woody fibres are themselves almost 'vessels,' are pitted, and do not contain starch, nor usually resin or other products. In examining the structure of jalap, it will be well to bear in mind that the tubers are sometimes exposed to considerable heat in the process of drying, and that the form and general characters of the starch granules, resin cells, etc., are often much modified thereby.

The adulteration of powdered jalap may be expected to consist of an admixture with the stems and damaged roots of the true jalap and of the substitution of or admixture with the powder of *Ipomœa Orizabensis*. This may be detected by its greater proportion of woody fibre, but more certainly by chemical analysis. And, secondly, by admixture of entirely foreign matter. 'Powder of post' is, I think, not so commonly used as ten years since, but starch of various kinds and ground guaiacum chips are, it is said, commonly used still. Of the latter I have no personal knowledge, and am inclined to believe that the sole commonly current adulterants are starches of potato and arachis, stems of *I. purga* and damaged tubers, and tubers and stems of *I. Orizabensis*. The starches and stems would be easily recognized by aid of the microscope by one familiar with the structure of the true tuber, and for the rest recourse should be had to chemistry.

CALUMBÆ RADIX.—The structure of the root of this menisperm is very simple, and will not give us much trouble. It consists for the most part of cellular tissue, with a few vascular vessels, a little woody fibre, and a few laticiferous vessels. The cells of the parenchyma are somewhat large, with very thin walls, very irregular and variable in both size and shape. Their contents are large starch granules, very variable in size and shape; sometimes single, but generally aggregate. The single ones vary in shape from nearly round to mussel-shaped. The aggregate granules are usually muller-shaped. As might be expected, the form and situation of the hilum is as variable as the size of the granule. The normal form appears to be a longitudinal furrow, but a single point or a 3- or 4-radiate slit or furrow are collectively as common. The polarization phenomena vary with the shape of the granule and situation of the hilum; but in all the single granules a black cross is very marked when the prisms are crossed. In the case of the aggregate granules, some little care is necessary in order that the cross may be seen. This starch, which is, with all its variability, characteristic, requires considerable care in preparing it for the microscope, owing to the great delicacy of the investing membrane of the granules. Glycerine jelly with a larger proportion of glycerine than usual, or glycerine and gum-water, is the best medium in which to mount it permanently.

The *pitted vessels* are large, by no means numerous or regularly distributed, and do not present any points of special interest. The woody fibres are of the usual unpitted type. The cells of the cortical layer in nowise present marked characters. Special canals, composed of short cylindrical cells, occur at intervals in the tissue, and contain a yellow-coloured substance, probably in chief part calumbine.

Adulterations of powdered calumba chiefly consist of starches, woody fibre, etc. These would be easily detected, as no common starch resembles that of calumba; woody fibre in quantity would at once betray an adulterant.

SENEGÆ RADIX.—The medulla is doubtfully present in the majority of specimens. There are no medullary rays in the specimens that I have examined.* The *wood zone* is composed of pitted vessels and pitted-wood fibre, closely resembling each other in all save size. The walls of these are very thin, and in cross section the wood zone has a somewhat reticulated appearance. The pitting of the wood cells and vessels is minute, in the vessels oval and transverse to their long axis. The wood cells taper slightly towards their ends. No cell contents beyond colouring matter. The layers of the *cortical zone* present the usual characteristics. The cells are more regular than is frequently the case, and are somewhat cubical in shape. The inner layers of cells are starch receptacula. The starch granules range in size from an exceedingly minute, sharp-edged polyhedric granule to a medium size (sometimes very large) roundish but flattened granule. They all give a black cross with polarized light, but great care and practice in the use of high powers with polarized light are necessary to enable it to be seen in the smaller granules. Adulteration doubtful.

(*To be continued.*)

SUPPLIES OF OPIUM AND SCAMMONY FROM TURKEY.

BY P. L. SIMMONDS.

Continued from page 987.

SCAMMONY.—From an elaborate and carefully prepared notice of the scammonies of the Turkish empire, submitted to the jury at the Paris Exhibition in 1867, I am able to furnish some interesting and valuable data as to the characters and varieties of scammony shown from different localities, and the results of careful examinations and analyses made of them by Dr. Della Sudda (Fayk Bey). I will first, however, give the official return of the imports of scammony into the United Kingdom during five years.

Imports of Scammony from Turkey.

	Quantity.	Value.
1866 . .	9,886 lb.	£15,479
1867 . .	9,341	13,843
1868 . .	7,367	9,403
1869 . .	5,827	6,991
1870 . .	25,592	30,761

Scammony is the produce of many species of convolvulus, which require no culture, growing spontaneously on the mountains and slopes of hills in nearly all the districts of Asia Minor. They prefer a dry and stony soil, springing among the brambles and thickets, up which they twine. By the commencement of April the young shoots appear, and in May and June the plants are in their full vigour. July is the favourable time for collecting the juice, which is obtained from the roots, the stems being rejected as useless and inert.

The roots are cylindrical, sometimes twisted round themselves like cords. The cortical plant is rugous, lightish red or ashy grey, adherent. The interior is compact, whitish, studded with concrete small drops of a light yellow colour, and riddled with round pores visible to the naked eye. In the month of July the natives, furnished with spades, knives, mussel-shells and other receptacles, proceed to the mountains or localities favourable for their search. Arrived at a suitable locality, they commence with the spade to free the roots of all substances which surround them, brushwood, earth, stones, etc. to a depth of about three or four inches. When this is done, they cut the large roots at their junction with the stem of the plant, and hollow it out so that the milky juice ascends and concretes in this receptacle, and is easily collected into the shells.

In the smaller roots and in other places incisions are made, to allow the sap to exude and drop into the mussel-shell, where it coagulates. Formerly it used to be dried and retained in these shells, and was called scammony "*de première goutte;*" and this kind is even now occasionally met with in commerce, but it has fallen into disuse, and the shells are only used as first recipients of the juice.

What is known as scammony of the second drop is obtained by expression, which is carried on in the following manner:—The entire roots are taken up, cut into pieces and pounded, so as to obtain the juice easily. This when solidified, shaped into lumps and divided into irregular pieces, constitutes the principal part of the scammony of commerce.

This process is becoming more general, and would not be objectionable if care were taken to remove the vegetable substances before solidification, and the fraudulent practice of adding flour or other adulterants, under the pretext of rendering it more pure and merchantable in appearance, were omitted.

Authors differ much in their classification of scammonies and the names given; some would distinguish them by the place of origin, some by the variety of plant from which they are obtained, while others would range them according to the characters and physical properties which they possess. Each give such good reasons for justifying their opinions, that it is difficult to know which to follow. But the Director of the Central Civil and Military Pharmacy, Constantinople, who has had large and favourable experience for studying the subject, tells us that he has seen the same convolvulus furnish at Aleppo (a locality much vaunted) a scammony inferior to that of Rhodes, of Mount Lebanon and of Amassiah; that he has had under his hands scammonies of the same colour, the same appearance, presenting in a word identical physical characters, the one occupying the top and the other the base of the scale as regards the proportion of resin. In conclusion it may prove valuable to give a digest of his analyses of eighteen varieties of scammony and some few roots from different localities.

1. Rhodes.—This scammony was in the form of a flat cake, very friable, with a brown and vitreous fracture, studded here and there with grey spots, whitens with the saliva, gives neither to the taste nor after taste any bitterness, burns at the lamp with flame, and continues to burn some time when removed, if not extinguished. Resin 76·95 per cent. Residue starch and silica.

2. Kianguiri.—Scammony in small, irregular fragments, of a deep brown, fracture conchoidal, does not blanch with the saliva, burns without flame at the light with a slight sputtering. Resin 70·15. Residue, starch and silica.

3. Aleppo.—Scammony in fragments, rather large, of a greyish appearance on the exterior and a mixed brownish-grey in the interior, whitens with the saliva,

* It is worth while to mention that the upper portion of roots frequently have both medulla and medullary rays when these are absent in the lower portions of the root. When, therefore, I speak of the absence of medulla, I refer to the root, excluding its uppermost portion.

very resistant, fracture irregular and dull, only burns with a little flame when close to the lamp, and dies out when removed. Resin 49 per cent. Residue, starch, carbonates and silica.

4. Ismid.—Scammony of a yellowish-brown colour, blanches with the saliva, is very little friable, semi-transparent in thin sheets, burns without flame at the candle, and gives off an odour like burnt potato. Resin 39·82. The large proportion of residue shows abundance of starch, extractive matters, carbonates and silica.

5. Smyrna.—Scammony in irregular fragments, of a deep brown, very friable, irregular fracture, presenting cavities here and there, whitens very little with the saliva, burns with a flame at the light, but goes out on removal from it. Resin 61. Residue, starch, carbonates and silica.

6. Sivas-Amassiah.—This scammony arrived in the form of a great oval cake 18 centimetres long by 12 broad and 4 or 5 thick. The mass was compact, had a conchoidal fracture, purple-brown throughout, did not blanch with the saliva. The splinters had a dull yellow semi-transparent colour. Burns with flame and bubbles or spits at the light, soon extinguishes when removed, giving off from the ash a disagreeable odour. Resin 72. Residue, starch, carbonates, oxide of iron and silica.

7. Koniah, Gulnar.—Scammony in irregular fragments, some of a greyish brown, others of a dull grey, porous fracture, does not whiten with the saliva, burns at the light without flame, and speedily goes out with a disagreeable odour. Resin 55. Residue, starch, carbonates and silica.

8. Broussa.—Scammony in fragments of an ashy grey colour, a dull fracture, burning at the light without flame, blanching very little with the saliva. Resin 51. Residue, starch, carbonates in abundance, with a little silica.

9. Broussa, Yecaditz.—This scammony was received in the milky state, enclosed in a tin box well soldered; on opening, in consequence of excessive fermentation, it burst out in all directions. The juice was of a yellowish white, but darkened on oxidizing in contact with the air. Dried in a stove, it settled into irregular fragments of a bluish-black colour, with a brilliant fracture, very friable, blanched with the saliva, without having any bitter taste, burnt with flame and sputtering, but without odour. Resin 76 per cent. Residue, starch, vegetable detritus and carbonates.

10. Kutahiah.—Scammony in very irregular fragments of a deep grey colour, fracture dull and porous, whitens with the saliva, pretty friable when the piece was not too large, burns at the flame, and gives out a disagreeable odour, Resin 47·80. Residue, starch and silica.

11. Aleppo.—Scammony in irregular fragments, dull and porous fracture, of an ashy grey colour, blanches with the saliva, burns without flame and without any pronounced odour. Resin 66. Residue, starch and silica.

12. Angora.—This scammony was received in a small cup, in a very compact mass, which only yielded thin scales to the efforts of the knife, of a clear brown, whitening with the saliva, and burning at the light with flame. Resin 86. Residue, vegetable detritus, carbonates and silica, and traces of starch.

13. Angora.—Scammony in irregular fragments, of a clear brown, clean fracture, very friable, blanches with the saliva, burns at the light with flame and spitting, continuing illumined when removed from the light, and giving off a disagreeable odour. Resin 46·87 per cent. Residue, starch, carbonates and silica.

14. Gueive.—Scammony in irregular fragments, grey at the surface, black speckled with grey in the interior, very friable, bleaches with the saliva, burns at the light with flame and sputtering, but dies out when removed from the light. Resin 48·36. Residue, starch and silica.

15. Mount Lebanon.—This scammony was received in the shape of a round compact cake, of about 15 centimetres diameter by 3 thick; whitens with the saliva, burns without flame at the lamp, giving off a disagreeable odour. Resin 74·60. Residue, vegetable débris and carbonates, but no trace of starch.

16. Koniah-Antalia.—Scammony in irregular fragments of a deep grey colour, porous fracture, does not whiten with the saliva, burns without flame at the light, giving off a disagreeable odour. Resin 54. Residue, starch, carbonates and silica.

17. Skilip.—Scammony in irregular fragments, of an ash-grey at the exterior, and a dull brown at the interior, tolerably friable, does not whiten with the saliva, nor burn at the candle. Resin 36·14. Residue, starch and silica.

18. Houdavendiguiar.—Scammony in mussel-shell, known as "première goutte." Colour at the surface bluish-black, brown in the interior; it burns without odour or flame at the light, bleaches with the saliva. This scammony presents the same characters and properties as that described under No. 9, and when we find that they come from the same district, we may conclude that it is the same product sent in different forms. Resin 71. Residue, vegetable detritus, starch and carbonates.

I now have to speak of the composition of a few of the roots submitted to examination.

Bagdad-Himalaya.—Root of a yellowish-white, of the thickness of the wrist, very light, and presenting in some places considerable protuberances; bark rugose, and largely furrowed, detached easily in thin sheets superposed. The interior, which differs little from the exterior except in colour, presents ligneous fibres, separated by the destruction of the cellulose. This root appeared to be destroyed by larva, and dead at the foot; 100 grams pounded and treated with alcohol, gave no result.

Koniah.—This root was soft, of the thickness of the finger, of a madder-root colour, yellow and porous in the interior; 50 grams pounded and treated with alcohol gave a liquor which, on evaporation, yielded a residue composed almost entirely of extractive matters, agreeable to the taste, purgative in a dose of 1 to 1½ gram, but so hygrometric that, left in the dry state exposed to the air, it liquefied in a few hours. The only root met with of this kind.

Smyrna.—This root was long, straight, and of the thickness of the thumb, of a light grey at the exterior, and yellowish within, and presenting in the parts severed all the pores blocked up with resin, the portion taken being the centre, excluding the extremities; 62 grams pounded and treated with alcohol deposited, on evaporation, 7 grams 22 centigrams of a dry product composed of gum-resin and extractive matters, which, left exposed to the air, continued in the dry state. This resinous extract was found to be a good and mild purgative in the dose of 1 to 1½ grams. Resin 11·64 per cent.

Angora-Bozouk.—This root was of a madder colour exteriorly, and yellowish in the interior, cylindrical, 10 centimetres long by $2\frac{1}{2}$ in diameter; 40 grams of the pounded root treated with alcohol yielded 4 grams 20 centigrams (or 10·30 per cent.) of a purgative substance so hygrometric, that it became syrupy when exposed to the air.

Alep Isladé.—Root of a dark grey exterior, yellowish in the interior, ligneous and very porous; 50 gram of the root treated with alcohol gave a percentage of about 5·40 of a purgative product very hygrometric.

To summarize this inquiry, it is clear from the careful researches made, that the great difference in quality which exists between one kind of scammony and another, is due less to the nature of the soil, or the varieties of the plant which produce them, than to the defective modes of extraction of the milky juice, and the successive manipulations to which it is submitted.

A fact which is lost sight is that the root is long-lived, though the stem is annual, for it does not attain its full development till after the space of several years, and it is only after the third or fourth year of growth that the juice is completely saturated with gummy resinous substances. The extraction by expression is the most useful and practical.

By selecting the most healthy-looking roots, cleaning and cutting them, and submitting them to a gradual pressure in a canvas bag, two men will obtain in two days more than four will procure in eight days by the old method of incising the root.

CARBOLIC ACID AND CREASOTE.

BY PROFESSOR FLÜCKIGER, BERN.

A good plan for distinguishing these two substances is as follows:—

		Parts.
Take	*a*. Solution of Perchloride of Iron about 1·34 spec. gr.	1
	b. Creasote, that is to say, the liquid to be tested for Creasote	9
	c. Alcohol, containing about 85 per cent. of absolute Alcohol	5
	d. Water	60

Now $a+b$ mixed assume no peculiar colour.

$a+b+c$ furnish a green solution.

$a+b+c+d$ form a turbid mixture of a dingy brownish colour, drops of creasote being separated.

On the other hand, in the case of carbolic acid, suppose likewise,—

a. The above ferric solution, weighing equally	1
β. Carbolic Acid (phenol)	9
γ. Spirit of Wine, as above	5
δ. Water	60

Now $a+\beta$ will show a yellowish hue.

$a+\beta+\gamma$ yield a clear brown liquid.

$a+\beta+\gamma+\delta$ display a beautiful permanently blue solution, without separation of carbolic acid, or the few drops sinking down may be redissolved by shaking.

Mr. Th. Morson pointed out* that glycerine is also a good test for the purpose under notice, creasote being not or almost not soluble in that liquid, whereas, as it is well known, carbolic acid readily mixes in all proportions with glycerine. This notice, however, requires, I beg to observe, a slight modification. True creasote, which stands the above test, is perfectly miscible in any proportion with anhydrous or nearly anhydrous glycerine, but it is not so with a somewhat diluted glycerine; a clear solution of creasote and of the same weight of anhydrous glycerine becomes turbid on addition of a little water, whereas a similar solution of carbolic acid may be diluted with water without separation of carbolic acid.*

The blue colouration of carbolic acid, due to perchloride of iron, enables us to discover it when mixed with creasote, but not to prove the presence of creasote in carbolic acid. The latter question, however, seems to me of less practical importance; yet, creasote, if present to some extent, would quickly separate in the above process, $a+b+c+d$, if more water be added. For this purpose the addition of perchloride of iron would be useless.

* Pharm. Journ., May, 1872, p. 921.

* The glycerine employed by Mr. Morson was the ordinary distilled glycerine of commerce, and he considers the advantage of the test suggested by him to consist in its simplicity and easy application.—Ed. Pharm. Journ.

CHINESE CHEMICAL MANUFACTURES.†

BY F. PORTER SMITH, M.B.

There is a body of men in China called Taouists, the professed followers of *Lau-tsze*, the great philosopher of China. Their studies have embraced every department of knowledge, including especially the subject of alchemy, as an art and as a science. The Rev. J. Adkins, a veritable Christian Taouist, pointed out in a communication made to the Hongkong Branch of the Royal Asiatic Society in the year 1855, that alchemy was pursued as a practical study for two centuries (?) before the Christian era, and for several centuries after that period. He argues from the facts that, as the Chinese were possessed of this knowledge long before alchemy was studied in the West, and the Arabian or Mohammedan traders who were the reputed discoverers of this art, had frequent and early intercourse with China by land and by sea, this interesting branch of knowledge was borrowed from the Chinese as the first professors of this true science. In the pursuit of some flux by which the dross of animalism was to be purged away, and the higher part of man's nature to be crystallized out and sublimed into some stable and eternal form, these Taouists practised fasting, discipline, worship, the use of charms, and the search for a sovereign remedy for all the ills of life. More essentially Chinese than the followers of Confucius, these students of nature started with the study of that oldest scientific book in the world, the *Yih King*, or Classic of Changes, hoping to wring from it some reply to their deep-searching cry for the truth as it is in nature.

Referring to the 'Notes on Chinese Literature' by Mr. Wylie, we gather that the earliest work now extant on the subject of alchemy is the *San-t'ung-k'i* by *Wei Peh-yang* of the second century after Christ. *Koh-hung*, better known by the name of *P'au-p'oh-tsze*, who lived in the *Tsin* time, during the close (in the early part of the fourth century after Christ) of that dynasty, was a voluminous author on alchemy, materia medica and other kindred subjects. He is largely quoted in the *Pen Ts'au Kang Muh* as an authority on chemical and medical subjects. Many other authors have included the subject of transmutations in their writings.

As the result of these researches, pursued with all perseverance, but no success in finding the Elixir of Life or the Philosopher's Stone, the Chinese of the

† Reprinted from 'Transactions of the North China Branch of the Royal Asiatic Society.'

present day have a number of exceedingly simple and economical processes by which they obtain tolerably pure mercurial and other preparations, of the greatest service even in their now unskilled hands. Their apparatus is of the very rudest character, and their materials are often of the most unexpected kind, but with these they can manufacture calomel and vermilion of the most beautiful description.

The manufacture of enamels and porcelain formed another field of chemical research, carrying them to the same effective results, produced they knew not how or why. The taste for colouring vessels, walls, scrolls, and some few other objects led them to the study of the metals iron and copper, from which they extracted red and blue pigments. The manufacture of fire-works has been also a means of increasing their chemical knowledge. These artists, called *Yen-ho-kia*, learnt the use of iron, camphor, and other secret substances, by the addition of which the flame is altered or intensified. It has been long known to these numerous manufacturers that by the addition of a small quantity of arsenic, the noise of crackers is rendered much louder and sharper. The preparation of pigments for artists, of whom there are described in authentic works some 1607 celebrated names, has been a stimulus to the manipulation of minerals. To this day the Chinese White is to be found in the colour-artists' shops all over Europe as the best pigment of that description. The manufacture of ink, that most potent agent, has led to several curious observations of a chemical nature, of which more presently.

Much trouble is often taken by members of the Sinological order to invent new names for old things to China. Chemists have been known for hundreds of years in Chinese works as *Tan-lu-kia*, or *Tan-tsau-kia*. The name *Tan-kia*, a shortened form, as well as the other terms, is applied in works to what may be called the manufacturing chemists of China.

A very fair chemical nomenclature may be constructed out of the plentiful terms quoted in the *Pen Ts'au* from the writings of these alchemists and physicians. *Tan* stands for oxides, when preceded by some specific character. This word does not mean exclusively a red substance, such as cinnabar, but may mean some yellow, white, or red preparation. The dot in the centre of the character stands for the fire, that servant of the alchemist, and the rest of the character, sometimes written in the inverted form with the legs turned up, will do for the furnace, or crucible of the operator. *Fan* is the equivalent of the old chemical word vitriol, or a sulphate. Other similar terms may be found to express many conditions of inorganic matter, by those willing to search for them. Something like a hint at testing substances is found in the *Pen Ts'au*, where the antipathies of drugs are treated of. The extrication of ammonia when lime is heated along with sal ammoniac, the discoloration of silver and salts of lead by sulphur, and other instances might be adduced as evidence of some vague notions of the reactions of chemical substances. Something like an attempt at the statement of the equivalent composition of substances is seen in one of the names of Æthiops Mineral, sometimes called *Rh-k'i-sha*, or the "two-natured salt."

It will be better now to proceed to the particular discussion of the subject in hand—"Chinese Chemical Manufactures,"—by taking them in detail.

In the making of gunpowder the Chinese have practised a good deal of chemistry unconsciously. The manufacture of nitrate of potash from the efflorescent salts which are found on the surface of the soil, and on walls and places charged with urine, is carried on on a large scale in China. The properties of sulphur are well known to Chinese writers. It is procurable in large quantities from the sulphur pits near Tamsui and Kelung in Formosa, as lately pointed out by Mr. Taintor in the Customs' Reports for 1869. The red amorphous sulphur, called *Shih-ting-chi*, probably produced by the accidental mixture of some fatty substance with the ordinary brimstone of commerce, is fairly described in Chinese works. The composition of Chinese gunpowder, called by them "fiery medicine," is not very different, in some cases, from that of English powder. The charcoal of the willow and the *Cunninghamia sinensis* or Chinese Pine, is used in the manufacture. The Chinese are aware of the disinfecting and insecticidal powers of sulphur and arsenic. They enter into the composition of pastilles for getting rid of mosquitos, and the good effects of the gases resulting from the burning of crackers as expellers of evil influences are appreciated by the Chinese in some quarters. The alkalies soda and potash are turned to some account, although nitre and soda, or natron, are often confounded together. Carbonate of soda is brought from Mongolia, where the soil is charged with this alkaline substance, and requires no manipulation to render it useful as a means of raising bread. Potash, or pearlash, obtained by burning the rank herbage of inland districts is also to be met with in China. Tsi-nan-fu in Shantung is, or was, the seat of this rough manufacture. Both of these alkalies are used in Pehchihli to make a coarse soap, a branch of chemical manufacture which might be well taken up by the Chinese, and subsidised by Missionary Societies. Ferrocyanide of potassium, a beautiful yellow salt, is made in Canton, and by Cantonese in other parts of China, by burning dry refuse of animal substances, such as horn-parings, to a red heat with pearlash and a quantity of iron filings in a covered crucible. The process is kept a profound secret, as far as possible. The importance of this salt, sometimes called yellow prussiate of potash, is its employment along with alum and sulphate of iron to make that beautiful dye prussian blue—called "foreign indigo" by the Chinese, who largely wear the livery of this Conservative colour.

(*To be continued.*)

THE DISTINCTIVE CHARACTERS OF RHUBARBS.

BY DR. CAUVET, PHARMACIEN MILITAIRE.*

Conscientious pharmacists, who prepare their own powdered rhubarb, know how difficult it is to distinguish between the true Chinese rhubarb and the root obtained in Europe by the culture of various species of *Rheum*. The dealers in these false rhubarbs prepare them with so much skill that they may be easily mistaken for exotic rhubarbs of superior quality. The points of resemblance, however, are superficial, all on the exterior; for, although it is possible to dress a root so as to give it the appearance of a true rhubarb, it is not easy to modify its structure, and all the indigenous rhubarbs, whatever may be the species cultivated and the care bestowed upon their cultivation, present the Rhapontic structure.

During a sojourn at Toulouse a pharmacien of that city submitted to the author a specimen of some rhubarb that he had received from a house of undoubted respectability, but with which, despite its handsome appearance, he was not satisfied. It resembled the variety of China called "flat," and its only apparent fault was that it was a little soft and did not crackle between the teeth so much as rhubarb of good quality. After removing the fine powder by which it was covered, it was noticed that its superior or convex surface did not present the white lines arranged in a delicate network that are seen in the true rhubarb, and that its inferior or flat surface was devoid of the characteristic stars that are always found in the Russian, and more rarely in the Chinese varieties. The absence of these two characters seemed to point to

* Memoir read before the Paris Société de Pharmacie, March 6th, 1872; (*Journ. de Pharm. et de Chimie* [4] vol. xv. p. 275).

a false rhubarb, and an examination of its structure was therefore made.

The root was sawn transversely across, and the section smoothed with a knife; it was then wiped lightly to remove the dust, and moistened with a few drops of water. Upon comparison then with a specimen of genuine Chinese rhubarb it was evident that it was obtained from a different source.

The following are the principal points of difference between the French indigenous, the Russian and the Chinese rhubarbs:—

French Indigenous Rhubarb.—A transverse section presents a rayed aspect, formed of alternate white and red lines, proceeding from the centre to the circumference, the white lines being a little larger than the red. Just

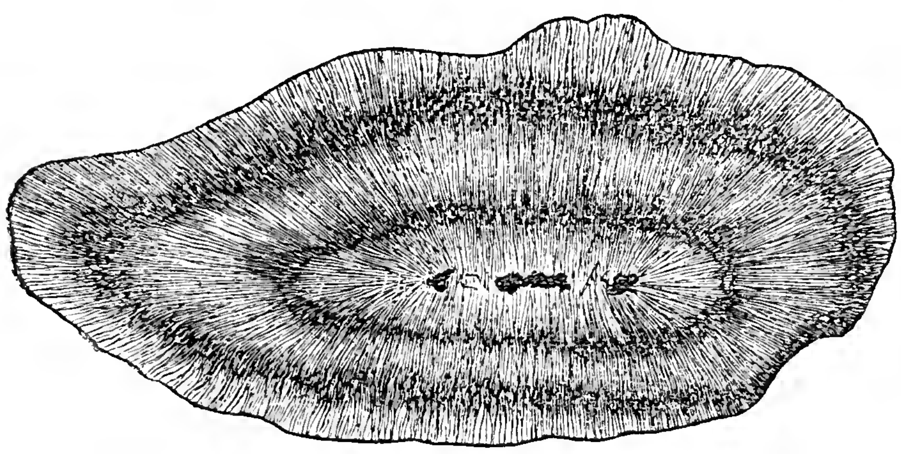

Fig. 1. French Indigenous Rhubarb: transverse section, natural size.

before reaching the circumference in circular pieces, or close to the edge in flat pieces, the radiating lines are cut by a brown zone, circular in the first, more or less interrupted in the second, but always visible.

Russian Rhubarb.—The transverse section of this root exhibits yellow lines upon a white ground, distinct, some times anastomosing, long or short, sinuous, often broken by radial systems. These star-like forms are circular or lengthened, and of variable size; their rays, clear yellow near the centre, become brown as they approach the circumference of the star, where they are generally of a very dark tint. As in the Rhapontic, the yellow lines run from the centre to the circumference; but this direction is ordinarily masked by the interposed radial systems and the flexuosity of the lines.

Chinese Rhubarb.—A transverse section shows light yellow rays proceeding from the centre to the circumference, and describing very flexuous lines. These lines appear often to anastomose, and form in the apparent anastomosis a sort of irregular star, the exterior side of

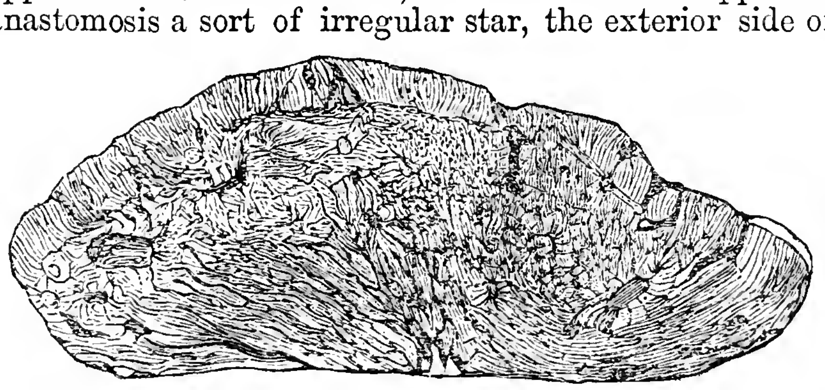

Fig. 2. Chinese Rhubarb: transverse section, natural size.

which is furnished with a greater number of rays than the interior. This disposition is seen principally in the cambium, and arises from the multiplication of the rays of the ligneous layer, which may be easily seen by means of a magnifying glass. As in the Russian rhubarb, the intervals between the rays are sometimes occupied by stars; but these are less numerous, less distinct, smaller and without the brown or blackish circle that characterizes the others.

If these three descriptions be compared, it will be seen that the French indigenous or false rhubarb is distinguished from the exotic or true by—

(1). The rectilinear disposition of its rays, which go from the centre to the circumference.

(2). The presence, upon its circumference, of a brown zone, relatively large and especially very distinct.

(3). The absence of the radiated systems (stars), so numerous in the Russian rhubarb, less frequent, but always easy to recognize in the Chinese.

In order to render these descriptions more easily comprehended, two engravings are given, one representing a transverse section of the French indigenous rhubarb, the other a transverse section of the Chinese. As the aspect of the latter varies with every root, and every piece of a root, it is only possible to represent its general appearance. On the contrary, the structure of the indigenous rhubarb varies so little that it is only necessary to examine one section, bearing in mind that the brown zone will be complete or not according as the specimen is an entire one, or only a portion of a root, or that it has been little or much cleansed.

LIQUOR FERRI DIALYSATI.

BY PROFESSOR G. DRAGENDORFF,

(Dorpat, Russia.)

I prepare the above in the following manner, which mainly is only a modification of the method of Grossinger:—By mixing 300 c. c. liquor ferri sesquichloridi of sp. gr. of 1·37, and 100 c. c. of caustic ammonia, sp. gr. 0·92, a mixture is produced, which after standing one or two hours, becomes perfectly clear and dark brown. It contains ammonic chloride and ferric hydrate dissolved in ferric chloride. From this mixture, subjected to dialysis, ferric chloride and ammonic chloride pass into the outer liquid, leaving upon the dialyser a brown solution of the colloidal ferric oxide. The latter is perfectly tasteless, and, as was shown by Graham, capable of being produced perfectly free from ferric chloride. (For 30·3 eq. of ferric oxide=Fe_2O_3 (Fe=28), he had 1 eq. HCl. Annal. d. Ch. and Ph., vol. 121, p. 1.)

This solution is used successfully under the above name, and it only devolves upon us to bring it to a definite volume, to render at least an approximate determination of a dose possible for the physician. This is the main difficulty in the way of preparing this substance.

The solutions of the colloidal ferric oxide possess, as has already been mentioned by Grossinger, immense powers of attraction for water. In the dialysing drum, as I used to employ it, made of parchment paper, I always observed, even if the level of the liquid within the dialyser was half an inch higher than that of the external water, not only a strong outward current into the water, but also the reverse from the water into the dialyser. In other words, the contents of the dialyser possessed a great tendency toward dilution from absorbed water. I hardly succeeded in obtaining solutions of ferric oxide containing over 4·5 per cent. Fe_2O_3+3HO, some containing only 1·5 per cent. I was forced, therefore, to abandon the previously used dialysing drum, and to place the iron solution into a pig's bladder, washed with dilute potash lye and then with distilled water. The bladder is filled through a funnel and then tied tightly as possible, so as to be almost completely filled by the solution. The better this is done the less water will enter the bladder during diffusion, and the more concentrated the liquor will remain. In this manner I succeeded in producing a preparation containing 7 per cent. of the ferric trihydrate. The great tendency of the contents of the dialyser to absorb water may be seen by firmly tying the opening of the bladder around a glass tube four or five feet high. In this the liquid will rise several feet above the level of the dialyser. The bladder containing the iron solution is suspended in a cylindrical glass vessel, with its upper portion about an inch below the level of the water, the quantity of which in the outer vessel should be at least four or five times that of the iron solution within the bladder. This exterior water is changed during the first few days every twelve hours, and later, every twenty-four. Well-water cannot replace distilled water during the first few days. The first diffused liquors, rich in ferric chloride, can be employed for the precipitation of the ferric oxide. The diffusion is continued with distilled water until, after one lasting twenty-four hours, nothing is dissolved, which upon the addition of nitric acid will be precipitated by argentic nitrate. In ten or fourteen days this result will be achieved. The iron solution contained in the bladder I suggest to dilute to 1000, when it will contain about 5 per cent. of the ferric hydrate of the above composition. Should too much water have entered the bladder, the liquor may be concentrated in a water-bath (or better, air-bath), at a temperature of 60° or 70° C. In most cases, part of the colloidal ferric oxide will during this process be changed to the normal oxide, and will separate.

The liquor ferri dialysati is best used without any addition, which is easily possible, as it is tasteless. Its dilution is only permissible with distilled water. Well-water at once causes a precipitate of the ferric oxide. Even the patient using the iron should drink distilled water afterwards, if he thinks it at all necessary. If the preparation is to be sweetened, this may be done with simple syrup. Sufficient white sugar may also be added to produce a syrup, but the solution of this sugar must take place at the ordinary temperature. If the solution is attempted at an elevated temperature, frequently a part or all the ferric oxide will separate from the solution, especially if the sugar be not perfectly white and free from lime.

The liquor ferri dialysati keeps well. I have preserved a sample solution of the same over four years, without having noticed any change. Also a sample of *syrupus ferri dialysati*, prepared by dissolving 120 parts of powdered sugar in 75 parts of the liquor, I have kept for several years without any apparent change. Grossinger has already called attention to the stability of such a syrup. I claim a superiority of these solutions of dialysed iron over those prepared by Hager's method, as mine contain less ferric chloride than Hager's. His proportion between muriatic acid and iron is 13 : 7. For children and weakly persons, I deem my preparation more useful.

A liquor *ferri phosphorici dialysati*, I prepare by mixing an aqueous solution of the officinal sodic phosphate with an aqueous solution of ferric chloride, and subsequent diffusion. After completion of this process a light brown solution is obtained, containing 3 per cent. ferric phosphate. The proportion of ferric oxido and phosphoric acid was established as 3 eq. to 1 eq.

This solution also is tasteless, and may be especially applicable for therapeutic use, possesing the merit over the solutions of ferric phophate ordinarily used of containing common orthophosphoric acid *i. e.*, phosphoric acid in the shape in which the animal body can best assimilate it. Also from this liquor I prepared a syrup by the addition of sugar in the above proportion. But this commenced to show decomposition in about two weeks. The liquid became gelatinous, and acquired an inky taste. After three or four months numerous algæ were found in the mixture.—*The Chicago Pharmacist.*

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.

BY C. R. A. WRIGHT, D.SC.

(*Concluded from page* 992.)

IV. *Action of Sulphuric Acid on Codeia and its Polymerides.*

The results detailed in the previous sections show that the action of sulphuric acid on codeia is to polymerize it, with the formation of di-, tri-, and tetracodeia, the substances obtained by Armstrong and by Anderson by this means being identical with the first and last of these bases; it appears probable that tetracodeia may be formed by the further polymerization of dicodeia, whereas it would seem as though tricodeia were not likely to be obtained from dicodeia; on the other hand, it is possible that tetracodeia is directly produced from codeia, and that it could not be formed from dicodeia. To settle this point, pure dicodeia was heated to very gentle ebullition with sulphuric acid diluted with its own bulk of water for five hours, the operation being conducted in a long-necked flask so that no appreciable concentration by evaporation took place. At the end of this time the dicodeia was wholly converted into a base, of which ether dissolved only traces; hence no tricodeia was formed. After precipitation by Na_2CO_3 and drying, the free base was dissolved in alcohol and fractionally precipitated by ether. If the alcoholic solution be nearly free from water, the ether throws down solid amorphous flakes; but if ten or more per cent. of water be present, the ether precipitate is a tarry fluid containing water, alcohol, and the base. Flakes of tetracodeia were thus obtained identical in all respects with that obtained by the action of phosphoric acid; a trace of some product of the further action of sulphuric acid appeared to be present, however, as the free base turned slightly green on drying, without, however, absorbing so much oxygen as to make any appreciable difference in its composition. Dried at 100°, 0·221 grm. gave 0·583 CO_2 and 0·142 H_2O.

	Calculated.		Found.
C_{144}	1728	72·24	71·94
H_{168}	168	7·02	7·14
N_8	112	4·68	
O_{24}	384	16·06	
$C_{144}H_{168}N_8O_{24}$	2392	100·00	

If the action of sulphuric acid be pushed further than this point, a smell of SO_2 is perceptible, and the product obtained rapidly oxidizes on precipitation by Na_2CO_3 and exposure to air. Nothing fit for analysis was obtained from the product, which probably is formed by the dehydration, oxidation, and possibly de-methylization of tetracodeia.

V. *On the Physiological Action of the foregoing Polymerides. By* REGINALD STOCKER, *M.B., Pathologist in St. Mary's Hospital Medical School.*

An aqueous solution of the hydrochlorate of codeia and its polymerides was in each case employed, being subcutaneously injected into adult cats (a dog being also employed in a few experiments), quantities equivalent to 0·1 grm. of the anhydrous salt being used in each experiment. Four cats were employed, several trials being made with each animal, and three or four days being allowed to intervene between each experiment, so that the effects of one dose had entirely passed away and the animal entirely recovered before the administration of another dose. The main results observed were as follows:—

Codeia.—Four experiments. In each instance dilated pupils; cerebral congestion (determined by ophthalmoscopic examination), and much increased reflex excitability (epileptic convulsions in one case); salivation and purging in two cases; vomiting not produced in any case.

Dicodeia.—Two experiments. In each instance vomiting; fundus of eye not congested; pupil dilated in one case.

Another experiment with a dog (full-grown she-terrier) produced salivation and purging without vomiting; no cerebral congestion.

Tricodeia.—Three experiments. In each case salivation (profuse) and dilated pupils; no cerebral congestion; in one case slight excitement; in the others purging and depression; vomiting produced in one of these two latter instances, micturation in the other.

Tetracodeia.—Four experiments. In each case profuse salivation, micturation and depression; dilated pupils in three instances, and lachrymation in two; in one case vomiting and purging; in another increased reflex excitability with an occasional convulsion (cat was weak and not in good condition); slight hypnotism in two cases.

In two experiments with the dog, salivation and depression only were produced.

From these results it would appear that codeia produces cerebral congestion and increased reflex excitability without vomiting; whilst di- and tetracodeia produce profuse salivation and some depression, with vomiting in several instances; no evidence of cerebral congestion and but little of increased reflex excitability being noticeable.

VI. *Conclusions.*

The foregoing results suggest the probability of other bases being capable of forming similar polymerides. In anticipation of this result experiments are in progress with morphia.

Hesse has shown that by the action of HCl on thebaine, there are produced two isomerides of that base, one forming crystalline salts, one amorphous salts; not improbably these are respectively dithebaine and tetrathebaine.

Matthiessen and Foster have shown that cotarnine occurs in crystals of the formulæ—

$$C_{12}H_{13}NO_3+\tfrac{1}{2}H_2O \text{ and } C_{12}H_{13}NO_3+H_2O;$$

and the writer's observations indicate that the former substance is more stable than the latter, which rapidly become more or less coloured; not improbably these two forms are polymerides, the first being $C_{24}H_{26}N_2O_6+H_2O$, the second $(C_{12}H_{13}NO_3)n\ nH_2O$. Opianic acid, on heating, furnishes an anhydride of formula $C_{40}H_{38}O_{19}$; this tends to show that the formula of this acid is not less than—

$$C_{20}H_{20}O_{10};$$

not impossibly, therefore, the formula of narcotine may

be double that usually ascribed to it; from their physical properties it is not improbable that the dimethylnornarcotine, methylnornarcotine, and nornarcotine of Matthiessen may be derivatives not of ordinary narcotine, but of its polymerides.

The different modifications of the cinchona alkaloids are not impossibly polymerides of one another.

The preceding Table exhibits the principal differences between codeia and the polymerides above described.

PUTREFACTION.

BY DR. F. CRACE-CALVERT.

An investigation into the origin and causes of putrefaction, and the modifications to which the phenomenon is subject under varying circumstances has for some time engaged the attention of Dr. Crace-Calvert, and in a series of papers recently read before the Royal Society are recorded some of the results attained, which present many points of great interest.

That a solution of albumen from a new laid egg, in pure distilled water, sealed from contact with air, presents no signs of protoplasmic life, after being kept some time while the same solution when exposed to the air for a short time, contained globular bodies having independent motion, had previously been stated by the author, but he has now pushed this inquiry further, and found that the rate of development of vibrio-life is proportional to the extent of surface exposed. The relations in which atmospheres of different gases stand to the development of vibrios have been tested by placing equal quantities of a solution of albumen in Manchester water into five glass bulbs, leaving one exposed to the air for twenty-four hours, passing either oxygen, hydrogen, nitrogen or carbonic acid over the others, and afterwards hermetically sealing them. The bulb containing oxygen speedily became turbid, then that containing air; the other three remained clear. On opening them, in the tubes containing air and oxygen, vibrio-life was found to be plentiful; in those containing nitrogen, carbonic acid and hydrogen the quantity was small,—in the hydrogen least,—apparently proving that oxygen is an essential element in the production of putrefactive vibrios. The animalcules themselves when kept in closed tubes seem to produce sufficient carbonic acid and other gases to exclude oxygen and arrest their own development, but their activity returns upon fresh contact with air.

The following is, according to Dr. Calvert, the *order* in which the development of this low order of life takes place. A few hours after the impregnation of albuminous fluid, "monads," $\frac{1}{128000}$ of an inch in diameter, appear to form in masses. These are gradually changed into "ordinary vibrios," at first attached to the mass, although having independent motion, but ultimately separating and each vibrio, in size about $\frac{1}{20000}$ in., enjoying a distinct existence. These gradually grow into "long vibrios," $\frac{1}{6400}$ in. in length. The "long vibrios" are in their turn changed by a process of subdivision into what appear to be nothing more than cells, which have considerable swimming powers. When this process is completed (in about twelve or eighteen months), it is found that a deposit has been formed appearing under the microscope to consist of shoals of particles of matter having no life, and the solution has become clear, possesses considerable refractive power, and is no longer coagulable by heat. No putrid odour is emitted by the solution until after the above deposit is formed, and the odour is in direct ratio to the number of vibrios present.

Another series of experiments was undertaken by Dr. Calvert to ascertain the relative power of various substances in preventing putrefaction and the development of protoplasmic and fungus life. Small test tubes were thoroughly cleansed, and 26 grams of solution of albumen placed in each, together with ·026 gram of the substance the action of which it was wished to ascertain. These tubes were kept in a room at a temperature of from 12·5° C. to 15·5° C., and every day a drop from each tube was examined under a microscope. The following is a summary of the results:—

	Days required for development of Fungi.	Vibrios.

Charcoal	21	9

In a similar series of experiments where gelatine was substituted for albumen, the standard solution contained far more abundant life during the 47 days that observations were made, and a distinctly putrid smell was emitted after 26 days. With bleaching-powder introduced, life did not appear until the twentieth day, and at no time was it abundant; no putrid odour being detected, and only a mouldy one on the thirtieth day. With chlorine solution, vibrio-life was observed only after forty days, and no putrid or mouldy smell at any time. With protosulphate of iron, neither protoplasmic nor fungoid-life appeared. With arsenious acid, animal life appeared after two days, but at no time were there any fungi. With the other substances the results were much the same as in the albumen series.

Finally a series of experiments was undertaken to ascertain the effect of the same substances in solution of albumen already swarming with microscopic life. It was found that cresylic acid immediately and completely destroyed the locomotive power of the vibrios. Carbolic acid, sulphate of quinine, chloride of zinc and sulphuric acid nearly destroyed the locomotive power of all the vibrios present. Picric acid and sulpho-carbolate of zinc left only a few that retained the power of swimming, but allowed them gradually to increase in number. Chloride of aluminium, sulphurous acid and prussic acid acted injuriously at first, but after sixteen days the solutions contained as much vibrio-life as the standard putrid albumen. Bleaching-powder, bichloride of mercury, chlorine solution, caustic soda, acetic and nitric acids, sulphate of iron, and the sulpho-carbolates of potash and of soda acted injuriously at first, but afterwards allowed the vibrios to increase more rapidly than in the standard albumen solution. Arsenious acid, common salt, chloride of calcium, chlorate of potash, sulphate of lime, bisulphite of lime, hyposulphite of soda, phosphate of lime, turpentine and pepper exercised no action upon the animalcules. Lime, charcoal, permanganate of potash, phosphate of soda and ammonia favoured the production of animalcules and promoted putrefaction.

THE SCIENTIFIC RELATIONS OF GERMANY, FRANCE, AND ENGLAND.

BY M. BERTHELOT.

In a remarkable article recently published in the *Temps*, by M. Berthelot, upon the relations that should exist between Germany and France, he argues that the great scientific results which have been attained in the past by the joint efforts of the scientific men of Germany, France, and England, are evidence of the importance to mankind of their still working in concord. We extract some of the principal passages:—

We know that modern civilization depends upon three nations, which should at all times and at any cost remain united,—namely, France, Germany and England, each with its peculiar genius and its share in the historic development of the human race. From the seventeenth century each of these nations has taken an active and prominent part in the progress of science.

To speak first of physical and mathematical sciences: though the initiative was due principally to a few men of other countries,—Galileo, an Italian, and Copernicus, a Pole, being the founders of modern astronomy and mechanics,—yet the development of these sciences was concentred chiefly in France, Germany and England. In France, Descartes discovered the methods of geometric analysis, which have proved more durable than his philosophical and cosmogonical theories. In Germany, Kepler invented the laws of planetary movement; and Leibnitz, who by education and the clearness of his conceptions, was perhaps more French than German, laid down the rules of the differential calculus under a form in which they still exist amongst us. At the same time, England produced Newton, greater, perhaps, in the science of nature, than either Descartes, Kepler or Leibnitz; for Newton discovered both new methods of calculation and the laws of astronomy, and since his time we have scarcely done more than develope his ideas and doctrines in studying the movement of the stars.

This same concourse of the three great nations of modern times is seen also in the foundation of chemical science, which in the present day plays so important a part, whether it be in the theories relative to atoms and the constitution of matter, to the formation of stars and of the successive layers of the terrestrial globe, to the origin of life itself; or, on the other hand, in the applications of human industry, dealing with metals, colouring matters, remedies, agriculture and manufactures.

Towards the end of the eighteenth, and at the commencement of the nineteenth centuries, chemistry was established upon a durable basis, after having floated during nearly two thousand years amongst mystical, obscure and incoherent notions. It was a Frenchman, Lavoisier, who fixed these indecisive ideas, by the definitive principle of the stability of matter, invariable in the nature and weight of its simple bodies. Perhaps, as has been asserted, Lavoisier did not discover any particular fact; but, according to Aristotle, principles and causes are things which are of more scientific importance, for by them we arrive at other knowledge. Now Lavoisier discovered the fundamental principle of chemistry: the science dates from him.

Is this saying that Lavoisier divined all, perceived all, traced for all time the plan of chemical science? Not at all; no more than that Newton alone founded astronomy. For this the inevitable concourse of the three great nations was required. Whilst Lavoisier published his immortal researches, the English Priestley and Cavendish discovered the principal gases and the nature of water,—inventions that were seized immediately by Lavoisier to support his theory. The Swedish Scheele brought also his precious contingent to the common work. Some years afterwards, an Englishman of genius, Humphry Davy, completed the edifice by the discovery of the alkaline metals, which he obtained by the application to chemical decompositions of the pile recently discovered by a great Italian, Volta.

Germany equally marked its place in the foundation of the new science. It was in the law of numbers that its work was principally characterized: Richter, Wenzel and the great Berzelius (a Swede) established the law of chemical equivalents, that is to say, a law as general and as absolute in chemistry as the law of Newton in astronomy. It is remarkable that the part of the Germans in this discovery has been principally experimental and practical, contrary to the opinion generally received of the German genius. On the contrary, the atomic theory, properly so called, of a character more abstract and more litigious, is due to an Englishman—Dalton; whilst its demonstration by the physical study of the gases, has been accomplished by a Frenchman, Gay-Lussac. This shows that the geniuses of the European races are not so different as has been asserted. Give them a common and equally high culture, and from each will proceed inventions equally original.

This conjunction of Germany, France and England is to be seen in every great epoch in the history of modern science. The demonstration could be carried down to the present time, proving that neither of these three nations has degenerated from its past: the doctrine of substitutions, the theory of the ethers, that of the polyatomic alcohols, dissociation, the idea of organic ferments, the methods of synthesis of organic principles, have been principally established by French discoveries; the theory of the radicals and that of the polyatomic elements are rather to be attributed to German discoveries; whilst the electro-chemical theory and the method of double decompositions have been invented in England. Finally, the great doctrine of the equivalence of the natural forces, more particularly designated under the name of the mechanical theory of heat, was first discerned by a German, Mayer, and an Englishman, Joule. Developed afterwards by a German mathematician, it has been established in chemistry principally by the experiments of French, English and Danish scientific men. But it would not be wise to dilate upon the science of the present day; we are too near to it, and are too much engaged in it for any estimate to escape suspicion of partiality.

In looking back over this short sketch of the progress of the science with which I am best acquainted, I would not ignore the part of Italy, which in the past was so great (may it resume its importance in the future!), nor that of the United States nor of Russia. But, I repeat, the initiative of the ideas and discoveries has rested for more than two centuries in the bosom of three nations —English, French and German. Their union and their reciprocal sympathy is indispensable, under the penalty of a general loss to civilization.

The Pharmaceutical Journal.

SATURDAY, JUNE 15, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE LAWS RELATING TO CHEMISTS AND DRUGGISTS.

THAT coroners and magistrates should prove ignorant of the details of the Pharmacy Act; that verdicts should be returned and censures passed upon persons who had strictly performed their duty; and that there should even be, through such ignorance, a possibility of the imposition of penalties having no justification in any Act of Parliament, was perhaps enough to raise the fears of the pharmaceutical body. But it is a matter for regret that great ignorance upon the same subject is to be found much nearer home; and it is most probable that amongst many members of the trade who have indignantly denounced the shortcomings of the authorities outside, there have been men who themselves, day after day, live on, lacking definite ideas on points of law of the greatest importance to all chemists and druggists.

Mr. GREENISH, in the paper on "Pharmacy in Austria" which he read at the May Evening Meeting of the Pharmaceutical Society, called attention to the fact that, in North Germany and Austria, a knowledge of the political laws which govern the practice of pharmacy is required of the student. He also remarked that, in this country, when questions arise affecting the interests of pharmacy, it is not until danger is at the door that pharmacists can be made to understand them. This is no less true of them in their individual than in their corporate capacity.

We are induced to call attention to this subject by the frequent occurrence of cases where chemists and druggists, either in themselves or their families, have suffered from the too late discovery of the real state of the law. There is no need to go far for illustrations. In this week's journal there is a letter from Mr. SMITH referring to the case mentioned by him at the Annual Meeting. We do not understand that he charges any harshness in the carrying out of the law, but that the law as it stands is harsh. If, however, the section providing certain exceptions had expressly included widows, there would still have been an appearance of harshness in debarring mothers and sisters. The hardship in the case in question undoubtedly arose from the deceased gentleman's want of acquaintance with the provisions of the Pharmacy Act.

But it is evident that there is no necessity for such cases in the future; and the requisite steps to avoid them appear to be much easier than an agitation for any alteration of the section. The question at issue is not affected by the fact that men do not like to arrange their affairs; though in this respect the experience imparted to DAVID COPPERFIELD after Mr. SPENLOW's death is scarcely an exaggerated picture.

But, there is another phase of the subject. Every now and then, men who would not wilfully do anything against the law, are surprised to find that they have acted illegally, and the information is sometimes made more impresive by the imposition of a penalty. Thus, only recently in a well-known town in the East of England, no less than eight or nine chemists and druggists, including the local secretary of the Pharmaceutical Society, were fined for selling methylated spirit without a licence. Moreover, the numerous questions that are continually addressed to us respecting licences, stamps, etc., show that there are many who have not yet made themselves acquainted with the contents of the Society's Calendar.

AMONGST the Communists recently executed at Satory was a man who had been convicted of participation in the murder of a pharmacien. The correspondent of the *Medical Times and Gazette* gives the following particulars concerning the crime:—

"The anniversary of the entry of the Versailles troops into Paris painfully reminded me of the dreadful scenes I had witnessed, and the unheard-of atrocities committed during the furious struggle between the insurgents and the regular army. Among the melancholy events that then took place I may mention that related of a pharmacien in the Rue de Richelieu, by the name of Koch, who was brutally murdered by the Communist soldiers simply because he refused to help them in raising a barricade in his neighbourhood. Not only did he refuse his aid, but he attempted to lecture them on their conduct, whereupon two of the men attacked him in his own shop. The pharmacien, however, true to his drugs, kept them at bay with a bottle of sulphuric acid in his hand, which he threatened to bespatter them with if they dared to touch him. The men, finding a dangerous weapon before them, beat their retreat, but soon returned with a reinforcement. The poor pharmacien, considering it would be useless to resist, was carried out of his shop, and, after a sham 'drumhead' court-martial, was ruthlessly shot in the presence of his wife and children, who implored the ruffians for mercy."

IN announcing the occurrence of a fire by which recently the shop of Mr. CHARLES YOUNG, chemist and druggist, Dundee, was partially destroyed, the local newspaper, following in the wake of its London contemporary, the *Times*, has sought to disseminate information concerning the origin of fires. In this case we are told that the fire is supposed to have been caused by the bursting and igniting of a bottle containing *vitriol or some other inflammatory substance.*

ST. JOHN'S WOOD and its neighbourhood is now added to the districts in which the pharmacists have decided to try the effect of shortening the hours of business, the public having been apprised that after July 1st, 1872, it is their intention to close their establishments at eight o'clock every evening (excepting Saturday), and entirely on Sunday and all Bank holidays.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

The undermentioned was received by the Board of Examiners on the 22nd ult., in lieu of the Preliminary examination.

Certificate of the College of Preceptors.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

A lecture on "Botany" was delivered by Mr. O. Corder at the rooms of the above association on May 29th; the President, Mr. A. Hill, in the chair.

The Lecturer said that it would be his endeavour that evening to try and help some of those who, seeking to attain the information which would enable them to rightly name botanical specimens, had discovered what a maze and mystery the many thousands of plants were to them, and the apparent hopelessness of their task. If, however, they did not attempt too much at the outset, but little by little, the task would be found no longer troublesome, but a true and lasting pleasure; and they would see in the different subjects that came before them in nature the marvellous adaptation of every part, —how the one was totally useless and helpless without the other. So students must help each other if ever they wished to attain any benefit by their pursuits. Much might be done by each one bringing plants for mutual examination, so that they might become to a great extent acquainted with the names of the flora of the district. But he might be met with the old cry, "All this is very well, but it would not be required for the 'Minor.'" He, however, wished them to get rid of all such thoughts, and to pursue the study of botany for the love and beauty of it. They would soon find to their pleasure that they had speedily and readily attained that which would help to carry them through both the Minor and Major with honour. He would further impress upon them that such knowledge, once attained by practical means, could never be altogether lost; and, however much it might appear beyond their requirements now, it would be very handy to be able to "inquire within" when information was desired. Sir William Hooker had well said that "the labour of compiling a flora of a country by a careful examination and comparison of specimens themselves, whether in a living or dried state, could only be appreciated by those who had been engaged in an employment of the same kind."

The collecting of materials in their native hills and valleys, upon the seashore, in the woods and among the majestic scenery with which the northern parts of this island eminently abound, generally in the society of friends of a congenial taste or students full of ardour and enthusiasm, was a very delightful occupation, especially when taken in conjunction with the anticipations of the pleasure that they might be able to bestow on kindred minds by sharing with them their discoveries and acquisitions. The more easy the commencement of a study was made, the more votaries would be drawn to it; and though they should attain no further knowledge than what had been already taught in the imperishable writings of a Linnæus or a Smith, yet they might be assured that in plants taken individually and in an isolated manner they would find subjects which would give ample scope for the employment of the talents of the greatest philosophers, in the due contemplation of which they might derive both pleasure and advantage to themselves, and be the means of communicating them to others.

The Lecturer then proceeded to point out the characters which required to be noticed, in order to lead to the recognition of the different plants, illustrating his remarks by reference to a numerous collection of specimens of plants and flowers, the more noticeable amongst which were *Podophyllum peltatum* and *Datura suaveolens* in full bloom.

After a vote of thanks to Mr. Corder, moved by the Chairman, and seconded by Mr. P. H. Mason, the meeting terminated.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

The above Association met at their rooms, Royal Arcade, Newcastle, on Thursday evening, the 6th instant., when Mr. George Foggon, read a very interesting and instructive paper on Castor Oil, illustrated by various diagrams and specimens both of the plant and dried fruit.

At the close of the lecture a considerable amount of discussion ensued, the chief speakers being Messrs. Shaw, Kerse, and Melhuish; after which a hearty vote of thanks was proposed by Mr. J. H. Proctor, seconded by Mr. H. Melhuish, and carried unanimously.

In the absence of the president, Mr. Shaw occupied the chair. There was a very good attendance of members present.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, June 6. In the absence of the President the chair was taken by Dr. Gilbert, F.R.S., Vice-President. When the usual business of the Society had been transacted, sixteen communications were read to the Fellows present, the titles being "On a remarkable Salt deposited from the Mother Liquor obtained in the manufacture of Soda," by Professor E. T. Thorpe; "On the Composition of Ceylon Jargons," by M. H. Cochran; "On a Double Sulphide of Gold and Silver," by M. M. Pattison Muir; "On the Solvent Action of various Saline Solutions upon Lead," by the same author; "On the Magnetic Sand of Mount Etna," by J. B. Hannay; "New Tests for some Organic Fluids," by J. A. Wanklyn; "Dendritic Spots on Paper," by A. Liversidge; "On Chinoline and Leucoline," by C. Greville Williams, F.R.S. A letter from Mr. Dewar, of Edinburgh, was then read by the Secretary, on some derivatives of Chinoline. Dr. C. R. A. Wright read a paper on the "Action of Phosphoric Acid on Morphine," and Mr. W. H. Perkin, F.R.S., a note on the "Secondary Colouring Matter produced in the preparation of Alizarine from Anthracene;" "On the effects of Temperature on the absorption of Gases by Charcoal," by J. Hunter, M.A. Dr. Armstrong then brought forward a series of "Communications from the Laboratory of the London Institution—No. V., On the Nitration products of the Dibromo-phenolsulphonic Acids; No. VI.: On Bromo-phenolsulphonic Acid; No. VII.: On the formation of substituted Nitro-phenolsulphonic Acids;" and finally the Secretary read a letter which had been received from M. E. Maumené, of Paris.

The meeting then adjourned until Thursday, 20th June, when Mr. H. Deacon will deliver a lecture "On Deacon's method of obtaining Chlorine as illustrating some principles of Chemical Dynamics."

SOCIETY OF ARTS.

April 24, 1872.

Nuts, their Produce and Uses.

BY P. L. SIMMONDS.

(*Continued from page* 980.)

The nuts of the sapotaceous plants yield a large amount of oil, especially the *Bassias* and the *Argan* of Morocco (*Argania sideroxylon.*)

The shea butter or solid oil from the Niger, is obtained from the fruits of *Bassia Parkii*, by boiling them in water. The yield of oil is about 30 per cent. The fruit of another species (*B. longifolia*), yield by expression in India the Elloopie or Mee oil, which is used for lamps among the poorer classes, and is one of the principal ingredients in making country soap. It is of a clear yellow, depositing stearine, density 0·912. The seeds of *B. latifolia* yield by expression a large quantity of concrete oil, called madooka, which is used in lamps, and for other purposes. The kernels are easily extracted from the smooth chestnut-coloured pericarps, when they are bruised, rubbed, and subjected to a moderate pressure. The oil concretes immediately it is expressed, and retains its consistency at a temperature of 95°. It is used locally for the manufacture of soap. It is usually of a greenish-white colour, and has been imported into this country under the name of mohwa oil, from Calcutta.

From *B. butyracea* a pure vegetable oil is produced, called choorie and galam butter. The kernels of the fruit are bruised, put into a cloth bag with a moderate weight laid upon it, and left to stand till the oil is expressed, which becomes of the consistence of lard, and of a delicate white colour. It is considered a valuable preservative when applied to the hair, mixed with some sweet scented oil. It makes excellent soap, and when pure burns bright, without smoke or smell.

There are one or two species of *Bassia* found at Gaboon, yielding 56 per cent. of oil. One, *B. gabonensis*, contains a true vegetable fat, of which two varieties are made, one called "noungu" by the natives, which has the consistency of goose fat; the other, named "djave," is only available for the preparation of soap.

The Borneo concrete vegetable tallow of commerce, judging from the cotyledons of seeds received, would seem to be from one of the *Bassias*. The fat is made up into large, round, flattened cakes, of the consistence and colour of cheese, and also cylindrical masses, which have assumed the form of the bamboo sections into which it had been poured when in a liquid state.

The nuts of *Coula edulis*, in Western Africa, yield 53 per cent. of an edible oil. The Booma nut of Central Africa much resembles an almond, both in shape and size, and with the fleshy covering is about the size of a walnut. It is probably the fruit of a species of *Vitex*. It furnishes an abundance of sweet bland oil, much used by the natives in their cooking.

In Jamaica a fine limpid oil is obtained from the bread-nut (*Omphalea triandia*, the *O. nucifera* of Swartz), but whether it will bear a low degree of temperature without congelation has yet to be ascertained. From another species an excellent oil is produced in Guiana, called ouabe, which is suitable for lubricating machinery.

Ground-nut oil is an important trade article, and the seeds enter largely into commerce.

The plant which produces the ground-nut (*Arachis hypogea*) is a little annual, one of a class which bury their pods in the earth when they ripen, instead of raising them into the free air. Having buried itself sufficiently deep, the pod then begins to swell, and when ripe becomes an oblong, rugged, pale-brown fruit, containing usually about two seeds, as large as the kernel of a hazel nut. It is now found in a state of cultivation all over the hottest part of the tropics. It was unknown until the discovery of America, and every region in the old world where it is now grown owes it to Brazil; so that we have in this plant a further example of the rapidity with which vegetables will take possession of soils where the climate is suitable, for it is now grown very generally in different parts of Africa, in India, the West India Islands, and the United States. The ground-nut, the staple product of the Gambia, is principally cultivated down the borders of the river.

In 1837 the export was but 671 tons, valued at £8000, but it has gone on annually increasing, for in 1860 it was 11,200 tons. The natives have, unfortunately, introduced of late years the pernicious system of beating or thrashing, instead of picking by hand, so that the nuts are mixed with leaves, stones, and other extraneous substances, causing large deductions in the French market, and also depreciating their value in the United States as an article of food, or rather as a favourite repast for the tables of the rich.

In Brazil it is known under the name of "amendoum," and has long been used there parched for food, and to extract oil from. This oil is used for cooking, medicinally for rheumatic affections, and for lighting.

The roasted seeds are sometimes used as a substitute for chocolate; and, according to Dr. Davy, they abound with starch as well as oil, a large proportion of albuminous matter, and in no other instance had he found so great a quantity of starch mixed with oil.

Dr. Muter, in an article in a popular periodical this month, after giving the following analysis of ground-nut meal, urges strenuously its more general use as an important article of food:—

Moisture	9·6
Fatty matter	11·8
Nitrogenous compounds (flesh-formers)	31·9
Sugar, starch, etc.	37·8
Fibre	4·3
Ash	4·6
	100·0

From this analysis it is evident (observes Dr. Muter) that the residue from them, after the expression of the oil, far exceeds that of peas, and is even richer than lentils in flesh-forming constituents, while it contains more fat and more phosphoric acid than either of them. On these grounds we are justified in urging the adoption of the ground-nut meal as a source of food, it being superior in richness of all important constituents to any other vegetable products of a similar nature. Although in the raw state it possesses a somewhat harsh odour, similar to that of lentils, this flavour entirely passes off in the cooking, and when properly prepared we consider that it has a very agreeable flavour. It has been tried in three forms:—First, boiled plain with water, like oatmeal porridge, and eaten with milk; second, made into a custard, with sugar, milk, and one egg to the pint; and third, washed, ground, and taken as a beverage, like cocoa. In all these three forms, but especially in the two latter, it was exceedingly palatable.

This seed is held in much estimation in the United States, where it is known as the pea-nut.

There are fully 550,000 bushels sold annually in the city of New York alone. Previous to 1860 the product of the United States did not amount to more than 150,000 bushels, and of this total nearly five-sixths were from North Carolina. Now North Carolina produces 125,000 bushels; Virginia, 300,000; Tennessee, 50,000; Georgia and South Carolina, each 25,000 bushels; while from Africa come about 100,000 bushels a year. In one week of the month of January, 1871, there were received at the port of New York 2751 bushels.

Another underground seed, passing under the names of rush-nuts, ground pistachio-nuts, chufas, souchet, etc., is *Cyperus esculentus*, the *amande de terre* of the French. They are eaten like nuts, being nutritive, restorative, and stimulant, and are also employed in the preparation of orgeat, a refreshing drink. The toasted roots have been used as a substitute for coffee, and yield a preparation resembling chocolate. In this country we have an earth or pig nut (*Bunium denudatum*, Dec.), which, being aromatic, sweet, and mucilaginous, might form occasionally an addition to our winter desserts, eaten raw, boiled, or roasted.

Under the name of candle-nuts, some considerable quantities of the seeds of species of *Aleurites*, an euphorbiaceous tree, now come into commerce. They are known to the French as bancoul-nuts; in the Pacific Islands they are called kukune. The natives of India are fond of the nut, which is said to be palatable, and something like our walnuts. It yields, by pressure, an oil of a density of ·923, which has various uses. It forms a good drying oil for painters, for, after boiling, it dries in about six hours. It is used for soap-making at Tahiti, in the place of cocoanut oil. It burns without that objectionable smell which cocoanut oil has, and gives a good light without injuring the lamp. It is used also as a drastic purgative. At Nukahiva the nuts are skewered together for lighting at night. The first burns for about ten minutes and communicates to the others, so that a row of 24 will last for about four hours. In the Marquesas and other islands, however, this mode of illumination is giving place to whale oil, purchased from the whale ships.

In the history of the 'Mutiny of the *Bounty*' it was stated that the rooms in Pitcairn's Island were lighted up by torches made of doodoe-nuts (*Aleurites triloba*), strung upon the fibres of a palm leaf, forming a good substitute for candles. These nuts are also so strung and used by the San Blas Indians in Central America, and a child is in attendance to knock off each nut as it becomes burnt out.

By an hydraulic pressure of 20 horse-power, 60 per cent. of oil can be obtained from the kernel of these nuts, but the shell has to be removed by heat or steam, being exceedingly hard to crush. One hundred kilogrammes of the nuts yield 33 of the kernels, and 100 kilogrammes of these, with proper pressure, will yield fully 66 per cent. of oil. The marc or oil-cake left is good for feeding cattle, or for manure. There is a species indigenous to the Eastern Archipelago (*A. malaccensis*), the oil of which is said to be used for culinary purposes in Java, which results, probably, from a more careful mode of preparation.

In China another species of *Aleurites* (*A. cordata*), known as the Tungshu-tree, yields such an abundance of oil that it is said to be one of the largest products of the province of Szechuen. In point of quality it is inferior to that of the camellia, but it is very extensively used for lighting purposes. The natives call it Tung-oil.

Beech-nuts, the seed or fruit of *Fagus sylvaticus*, serve to feed swine on now in forests; but before the general cultivation of cereals they were, like acorns, the food of uncivilized men. Dried and ground into meal, they make a wholesome bread; roasted, they form a tolerable substitute for coffee. A clear, yellow, inodorous oil is obtained from them in France; a bushel of beech-mast will produce about a gallon of oil, or the yield may be said to be 12 to 15 per cent of oil. In some parts of the Continent this oil is used instead of butter for culinary purposes. In the reign of George I. a petition was presented, praying letters patent for making butter from beech-nuts. It is a pity some wholesome vegetable fat cannot be brought into commerce in the present day, when butter is so dear and so bad. A beech-oil company was one of the most noted commercial speculations of Queen Anne's reign.

In Brazil the fruit of *Myristica bicuhiba* (Schott) yield a concrete oil, of a brown colour, which is employed in cases of asthma, rheumatism, tumours, etc.

A good quantity of the small oil nutmegs (*Virola sebifera*) have lately been imported. The seeds, bruised and pressed, by heat give 26 per cent. of a substance entirely soluble in potash water, fusible at 34·5, and composed of two parts of oil, one neutral and the other acid, the last forming about three-fourths of the mass. The neutral part, having glycerine for its base, forms a solid soap with soda. This oil is well adapted for candles. It is very abundant in Guiana, and deserves the attention of business men.

Physic-nut is a name for the seed in the capsules of *Curcas purgans* and *C. multifidus*, which furnish an oil used for lighting and in medicine.

It has the same qualities and uses as croton oil, and in large doses is a dangerous poison. The oil is largely used in Indian camps. It is odourless, of a deep yellow, and viscous, but burns well. When cold, it deposits a considerable quantity of stearine; density ·918. It is largely produced in the Cape Verd Islands, from whence nearly 300,000 bushels are annually shipped.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Friday, June 7th, 1872.

The Juries Bill.

On the application of the Attorney-General, it was ordered that the Select Committee on the Juries Bill have power to send for persons, papers and records; and that the report of the Select Committees on Special and Common Juries in 1867 and 1868, and on the Juries Bill in 1870, be referred to them.

Adulteration of Food, Drugs, etc., Bill.

The Committee on this Bill has been deferred till Wednesday, July 3rd.

The Public Health Bill.

These Bills, the Committees on which were set down for Monday last, did not come on that day, and up to the present time there is no further allusion to them on the notice papers.

Poisoning by Oxalic Acid contained in Black Draughts.

With reference to the case of poisoning by oxalic acid reported under the above head, at p. 1003, of last week's Journal, we have received a reclamation from Mr. A. J. Stedman, of 18, Castle Street, New Peckham. He states that he was the former proprietor of the shop in question, from whom Dr. Trail purchased it. But he expresses his surprise that it should have been represented that the draughts were the last of the stock purchased from him, since the quantity of black draught left by him,—which was not put up in bottles for sale, but was the remnant of a quantity kept for immediate use,—was not sufficient to supply seven months' demand; in fact, was not more than enough for a week. Moreover, as no spirit was used in making it, he considers that it would long since have become unfit for use.

Suicide by Battle's Vermin Killer.

On Sunday night, May 26th, a young woman named Mary Winnall, residing at Clatter Batch, committed suicide by taking a quantity of "Battle's Vermin Killer." It appears that she had been for a walk, and on returning home went to Mr. Hughes's, chemist, and bought a packet of "vermin killer," went home and took a portion of it, and died in a short time after. Two medical gentlemen were called in, but their services were of no avail. At the inquest Mr. G. Birt, M.R.C.S., said he was called to see the deceased, and found her in spasms, as if suffering from strychnine poison. He tried restoratives, but they proved of no avail. He had since analysed the powder produced, and found strychnine, and it contained sufficient to cause death. The death of deceased was caused by strychnine.

G. Darrell, assistant to Mr. Hughes, chemist, said that on Sunday night the deceased came to the shop from half-past nine to ten, and asked for a packet of "Battle's Vermin Killer," and he sold her a sixpenny packet. Deceased was quite collected, and not at all excited. The word "poison" was on the outside packet.

Evidence was also given that deceased had a "queer temper," and that she had said, on parting from her sweetheart, that he would never see her alive again; but no motive could be attributed for her committing suicide.

After a short consultation, the Jury found that "Deceased committed suicide while in a state of temporary insanity."—*Stourbridge Observer*.

Poisoning by a Baryta Compound.

On Friday, June 7th, Mr. Thomas Taylor, coroner, held an inquest at Bradford, touching the death of Wm. Lawrence, a cotton-warp sizer.

Dr. Isaac Mossop said he was called in to see the deceased on Thursday afternoon, and found him suffering from symptoms of irritant poison. The deceased was quite sensible, and said he had taken some chemical in mistake for Epsom salts. He said he had taken it at the works at which he was employed. Witness was not shown any of the chemical.

Some of the compound was here produced, and Dr. Mossop said it had, at a distance, the appearance of Epsom salts, but if the crystals were examined by any one who was acquainted with the appearance of Epsom salts, they would see a material difference. He was not aware of the nature of the poison until the deceased died. He treated the man for irritant poisoning, and he could not have done more if he had known the nature of the poison. The deceased died at six o'clock on Friday morning. Paralysis had set in, and witness had no doubt that death was the result of the paralysis of the voluntary muscles of the body. He had examined samples of the salts produced, and found that twelve grains would be sufficient to kill a dog and two drachms would kill a horse. A man had been known to die in an hour after taking an ounce of such poison. He had told the deceased how to treat himself, and he could not have altered the result if he had stayed in attendance on him until death.

The Coroner here read a circular referring to the poison, which stated that it was a sizing salt, to strengthen the warps, prevent dust, etc. The manufacturer and patentee, the circular stated, was Mr. A. Heald, 52, Dantzic Street, Manchester, and the name of the compound was "Heavy Baryta sizing Salts." The Coroner remarked that nothing was said in the circular from beginning to end that it was at all poisonous.

A Juror observed that if twelve grains would kill a dog, there must be thousands of grains given off the warps for which the salts were used when they were being manufactured.

Dr. Mossop explained that the salts were exceedingly soluble.

The Coroner: If they are soluble, there would be nothing much diffused but steam, and that might be pure water.

Mr. Seth Blakey, cotton warp sizer, said: I knew the deceased. He had been in my employment about fourteen years, as a cotton warp sizer. He took the management of the dyeing of the coloured work. The heavy baryta sizing salts came into my possession about a week ago. I had never used it before, but was going to make an experiment with it. The deceased along with the other foreman would see the circular sent with the salts.

In answer to a Juror, Dr. Mossop replied that he believed the salts would be injurious if taken in the pores of the skin. He believed he had read cases of death being occasioned by absorption.

Mr. Blakey said that the manner in which the salts were used did not necessitate the men touching it at all with their hands. The warps were sized and dried entirely by machinery. He did not know that the salts were poisonous. They were in the room where the deceased worked, and were open for the men to use just as they wanted them. He had learnt that one other man about the place mixed a teaspoonful with a pint of water and tasted it twice. The man did not take more than a a teaspoonful of the mixture, but suffered from severe vomiting. The deceased told him that he had taken a piece of the salts about the size of a bean in a glass of water. The chemical is not generally used in the dyeing business in Bradford, but it has been used in the cotton business at Manchester. The only thing he found fault with about the circular was that it was not mentioned that the chemical was a poisonous matter. Epsom salts were not used at his works, but they were used in some works.

Mrs. Lawrence said her husband left home about half-past six o'clock on Thursday morning. He was brought home about half-past ten o'clock. He said he had taken a little bit of Epsom salts in a glass of water, and some time after he felt an inclination to vomit. He vomited freely at the works, and when he got home and had some milk, he again vomited freely. It was two o'clock in the afternoon before he was seen by the doctor.

A conversation took place amongst the jury, and several of them expressed the opinion that it was reprehensible on the part of the patentee and manufacturer of the salts to send them out without a warning that they were poisonous. The Coroner said that there was certainly no criminality in the matter. The manufacturer did not send the chemical out to be taken in that way, and it appeared that in its proper use it was not necessary that it should be touched so that any injury might be done by absorption.

The Jury then agreed on the following verdict:—"That deceased was poisoned by taking a quantity of sizing salts instead of Epsom salts." The jury thought that a representation should be made to the manufacturer of the salts, to the effect that in their opinion he ought not to have sent it out without a notice that it was dangerous to life; and that they wished to condemn the practice of sending such things out without some precaution to prevent mistakes.

The Coronor said that Mr. Blakey had very properly opened communications with the manufacturer of the salts, and no doubt he would convey to him the opinion of the jury. Mr. Blakey intimated that he would do so.

The proceedings then closed.—*Bradford Observer.*

Review.

Elements of Chemistry, Theoretical and Practical. By William Allen Miller, M.D., D.C.L., LL.D. Revised by Herbert M'Leod, F.C.S. Part I. Chemical Physics. Fifth Edition, with additions. Longmans. 1872.

Miller's 'Chemical Physics' has been so long known and so justly commended as a text-book, that any further eulogy of it would be superfluous. The present edition differs but little from the last, the most important additions made by Professor M'Leod relating to Solar Chemistry, and the development of the theory of Atomicity.

Under the former head we have a very clear and interesting account, well illustrated by woodcuts, of the discoveries made during the last three years with reference to the solar chromosphere and protuberances. The theory of Atomicity is scarcely required in connection with the physical part of chemistry, and it would perhaps have been better to defer it altogether to the second volume, especially the very doubtful explanation of the variation of the atomicity or combining capacity of an element by *pairs* of units, the supposed universality of which has been disproved by the recent investigations of Dr. Roscoe on the chlorides and bromides of tungsten.

In connection with this subject we think it desirable to direct attention to a proposition (found also in the earlier editions) relating to the Law of Multiples and the Atomic Theory. On page 22, after the hypothesis of the atomic constitution of matter has been laid down in the usual terms, it is stated, as one of the consequences of this hypothesis, "that when the same elements unite in several proportions, these proportions must vary according to the terms of a *simple series of multiples*, since each atom of one element must unite with the other element in the ratio of 1, of 2, or of 3 atoms, or in some other ratio almost equally simple, inasmuch as the atom does not admit of subdivision."

Now, with all due deference to great authorities, we must submit that the conclusion here drawn does not follow from the premises. The theory of combination by juxtaposition of atoms does not necessarily imply combination in *simple* multiple proportions. What, indeed, is there in this hypothesis to preclude the possibility of 1000 atoms of one element laying themselves side by side with 1001, 1003, or 1007 atoms of another, or 1,000,000 atoms of one with 1,000,001, 1,000,003, etc., atoms of another, and so on, up to any conceivable degree of complexity? The indivisibility of the atoms has nothing whatever to do with the matter; for though an atom of A cannot actually combine with a fraction $\frac{m}{n}$ of an atom of B, there is nothing to prevent the combination of n atoms of A with m atoms of B, where m and n may have any integral values whatever. In other words, the atomic hypothesis is perfectly consistent with combination in any numerical proportions whatsoever. And, indeed, we need not search far for compounds exhibiting considerable degrees of complexity in their atomic constitution; such, for example, as the higher homologues of marsh-gas, the proximate principles of the animal and vegetable organism, or some of the derivatives of the opium alkaloids lately discovered by Dr. Wright. On the other hand, it is undoubtedly true that in a large number of important cases very simple ratios of combination are known to exist; but this we learn from observation, and not from any theory whatever.

We would not, however, be supposed to argue against the atomic theory; on the contrary, we regard it as indispensable to the systematic teaching of chemistry. All that we wish to point out is that, although this theory may have been originally suggested by the observation of certain simple cases of multiple proportion, and our belief in it may be strengthened by the observation of a large number of such cases, its connection with such simple proportions is by no means so *necessary* as is frequently supposed. Conclusive evidence of its reality is to be looked for rather in the phenomena of isomerism, and still more, perhaps, in physical phenomena, especially in the constitution and mechanical properties of gases, as viewed in connection with the dynamical theory of heat.

We cannot, however, here pursue the subject further; we merely throw out these hints for the further development which the atomic theory will doubtless receive in the second and third volumes of the work.

Before taking leave of this first volume, we think it desirable to direct the editor's attention to a matter of orthography. We observe in several places, in this, as well as in the former editions, the words "condens*i*ble" and decompos*a*ble." Now we should like to ask whether any one would write the corresponding substantives in the forms "condens*i*tion" and "decompos*a*tion."

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[315.]—MOUSTACHE POMADE.—In reply to the query, under the above head, for a pomade or paste that will darken the colour of a light or grey moustache, we are informed by a correspondent that it may be effected by the use of Condy's Fluid.

[316.]—REMOVAL OF STAINS.—In reply to A. R., the stains of pyrogallic acid and nitrate of silver on the hands can be removed by first applying a saturated solution of iodide of potassium, and then washing them in nitric acid diluted with twice its quantity of water. The iodide itself does not remove the stains, but on applying the nitric acid they soon disappear. A more expeditious and effectual way is to rub the stains with a lump of cyanide of potassium wetted with water, and as soon as they begin to disappear apply tincture of iodine to them, which will remove them at once; then wash the hands well to remove the cyanide; but the first I always find answers the purpose very well, and is not nearly so dangerous to use as the cyanide, which if there is an embrasure of the skin must not be used.—PHOTO.

[317].—BROWN HAIR DYE.—Will some skilful compounder kindly advise me the proper quantity of water to use for dissolving the acetate of lead in the "Brown Hair Dye," described in No. 4, PHARMACEUTICAL JOURNAL, July 23rd, 1870, p. 70.—F. B. J.

[318].—BLACK HAIR DYE.—I should be obliged if some subscriber would mention a "receipt" that will change the colour of the hair to a light black without staining the skin.—E. H.

TARAXACUM COFFEE.—We copy the following from a recent number of the 'Madras Mail':—"A gentleman writing to our Hills contemporary, about Taraxacum coffee, states that he has tried the beverage or remedy with the utmost success. He prepared it exactly as the coffee-bean is used; it was dried, boiled, or roasted, and pounded and used with coffee. One tenth part of Taraxacum to nine parts of coffee. This fortunate gentleman was entirely cured of diarrhœa arising from disordered state of the liver, and is as grateful, we should say, as Maria Jolly, who, 'after 50 years of indescribable agony,' was restored to perfect health, as the advertisements still attest, by the use of six boxes of Holloway's pills, and many pots of his ointment. This simple remedy is within every one's reach on the Hills, as the plant grows wild all over the Neilgherries. We should have thought some enterprising firm in Madras would by this time have advertised Taraxacum coffee for sale. We are not aware that the root even can be obtained in Madras, except prepared as an extract, which is about the most sickening thing possible as a beverage, tasting somewhat like extra flat ditch-water. We think a Taraxacum fizz, made palatable by lime-juice or raspberry vinegar, would make an excellent and popular 'Tonic Water.' Let the 'certified' chemists look to it."

LYCOPODIUM.—Lycopodium has been met with in American commerce adulterated with starch. This adulteration may be detected easily by the microscope, especially if the powder be viewed floating on water containing a trace of iodine.

The Proceedings of the Council.

Sir,—Permit me to inform the Council that it is not only possible but usual for the deliberations of representative bodies, charged with administrative and executive duties only, to be conducted privately.

Legislative functions, on the contrary, are properly exercised in public, but these are not within the province of the Council. Is it sufficient to quote the example of Boards of Directors, or does the practice of Committees of trades unions appear more to the point?

In reference to the proposed new bye-law, if anything so one-sided and intentionally offensive is brought forward, I shall move as an amendment, "that security against a hasty vote can only be effectually provided by a general poll, at which the votes of absent members can be recorded."

A Member before the Deluge.

June 11th, 1872.

Clause 16 of the Pharmacy Act.

Sir,—You have added a foot-note to my letter in your issue of June 1st, in which you say, "Mr. Smith appears to overlook the fact, that the widow to whom he alludes was carrying on the business of a chemist and druggist on her own account, and that she could not therefore claim the special exemptions provided in the Pharmacy Act of 1868." Permit me to ask in reply how I overlook this fact, when it is really the special grievance of which I complain? Why is the public to be so tenderly cared for, that a widow who succeeds by will to a business which it probably cost her husband a lifetime to work up, should be mercilessly deprived of it by law the moment the law has declared that it is hers by law and hers only? Clause 16 permits a trustee to carry on a business by means of a qualified assistant. Where is the justice of depriving a widow of the same privilege? Is the much-cared-for public likely to get any better protection from a trustee, who perhaps only unwillingly consents to act from respect to the memory of a friend, than from the widow who, with a qualified assistant, has every reason in the world to conduct her business with a due regard to her own safety as well as that of the public?

Since my letter appeared, I have received communications from all parts of the kingdom (to many of which it has been impossible to reply), expressive of alarm and astonishment that the law is as defined by the Act; while personal and pecuniary offers of assistance have been made to me for the purpose of inducing a reconsideration of this insidious clause; and I feel sure, from the general expression of opinion, that the subject will sooner or later enforce attention from its inherent importance; meantime, many may die in ignorance and leave their widows in the position of my poor friend, who, in a letter to me this morning, concludes thus,—"The more I think of it, the more cruel and bitterly unjust the law seems to be which drove me and my little ones from my home at ——," etc. I do not seek to draw attention to this seriously important question in my own interests only, because they are provided for; but surely it cannot be ignored by those who have any one to care for or a business to leave.

Wm. Fred. Smith.

June 10th, 1872.

[*** The hardship of the case referred to by Mr. Smith is undoubted, but the law on the point being perfectly clear, it behoves those who wish to avoid a sacrifice of their property to make such provision as to its disposition on their decease as will enable their representatives to avail themselves of the special exemptions provided by the Statute; this would be a much simpler way of meeting the difficulty than by agitation for an alteration of the law. Having said this much on the subject, we cannot again make reference to the particular case to which Mr. Smith alludes.—Ed. Pharm. Journ.]

The Sale of Poisons.

Sir,—I attended a sale of chemists' stock yesterday, of which I enclose a catalogue. Amongst the stock I saw about ℥j pulv. opii, ʒj morphiæ mur., ʒiv tr. conii, ℥iij ext. conii, ʒiv. tr. canthar., tr. hyoscy., and many other drugs of the same class sold for one or two shillings for the sake of the bottles.

Is it right that dangerous drugs should be thrown amongst the public in this indiscriminate manner? I saw one child playing with a bottle containing pulv. cambogiæ, and spoke to one of the men in the place about allowing drugs to be about in the careless manner they were. The answer was, it was not his fault; he knew nothing about them.

Is there nothing in the Pharmacy Act to stop such things, which are constantly occurring?

G. J. Girdler.

June 6th, 1872.

The Possibility of Effort.

Sir,—I received last week a letter similar to many with which I am favoured, containing questions which are at once difficult and a most unwelcome task to answer. The whole relates to our Examinations, and a desire is expressed that a clear and lucid understanding as to what is required should be given.

This particular topic has been so fully explained in the pages of our Journal, almost to weariness, that it may be dismissed with a simple reference to past numbers—the nature of the chief question will be best understood by the reply, which, as far as my light goes, I am constrained to make. I believe that when a young man has had but a scanty education, as evidenced by style of composition; when he is deprived of the aid and stimulus of local associations; when he has access to no lectures, and is guided by no teacher, and his sole help is derived from books, it is not possible for him to prepare satisfactorily for his examinations. I except genius—that can level Alps; and I am acquainted with the book of Mr. Smiles on triumph over difficulties; still, taking things on an average and the world as it is, we come back to the old narrative, "Understandeth thou what thou readest? How *can* I understand unless some one teach me?" Let me not, however, leave the subject without trying to set something right. Students aided only by books often fall into error by selecting elaborate treatises for their instruction; hence they distract their minds in inextricable mazes, in which they detect no plan, and out of which they see no exit. Pereira's Elements or Miller's Chemistry are excellent adjuncts to the lecture-room, and specially adapted to those more advanced, but works of simpler character should be chosen at the commencement. These voluminous compendiums dismay the tyro, they do him positive harm, and for all useful purposes a quiet dip in the Encyclopædia Britannica would do as well.

When a young man means to learn French, he conveys Molière, Racine, Corneille, Bossuet and other classic writers to the river to which he is most contiguous; then he attempts to fathom the mysteries of 'La Bibliothèque des Familles,' or probably asks Hachette what are the manuals at present used in a French infant school? So children learn; remember, my hopeful correspondent, that when you or I approach a science we are nothing else.

Joseph Ince.

Provincial Pharmaceutical Education.

Sir,—In the Journal for June 1st a letter appeared from Mr. Taplin, which, I think, contains the very best suggestion that has been yet made to meet a difficulty with regard to the above; but I would append to it, that if it is carried out, assistants now passing for their examination, and apprentices already bound, shall be able to avail themselves of the plan proposed.

I have great confidence, now my friend Mr. Schacht is elected on the Council, this very important subject will have their early attention, and that some satisfactory arrangement will be made to meet the wants of the assistants and apprentices throughout the kingdom.

John Martin.

Clevedon, June 4th, 1872.

Sir,—In a previous letter I stated that to aid the country schools would be very unfair; to support this remark, as well as to say a word or two upon another subject, is my object in writing again.

Unfair, first, to the Majors and Minors who have been induced to proceed to London and elsewhere to acquire a good pharmaceutical training, at very great expense to themselves; the aim of the proposed scheme being to make the obtaining of degrees easier and cheaper than it has been to those already passed.

Unfair, also, to members in business, that their subscriptions should be appropriated to a cause which they really do not care to support. Unfair to the registered apprentice who has passed his Preliminary examination, and paid his fees, since the country schools make no distinction between registered and unregistered students, but admit all to the course of instruction for the same fees, the unregistered not having to pay double fees for learning, as in London.

Unfair, lastly, to every one enrolled into the Society, on account of its not being a good general scheme.

Why should the members, associates or apprentices at Tadcaster contribute to a society which supports a school at Manchester, but not one in their own town or village, which has as good a claim for aid from the Pharmaceutical Society as any larger place has?

Were the scheme for Provincial Education a fair, possible, general and practicable one, not a murmur would be heard; but since it has been shown to be the contrary, discontent must be expected from a large number opposed to it. If the Society has more money in hand than it needs, let it return to its members a percentage of the fees already contributed. A few days ago we heard in a whisper what we must expect to hear in a loud tone by-and-by, "Give me back my money."

A good deal is now said about payment on results; but he who proposes to give the pharmaceutical teacher payments on the results of the examinations cannot have received payments on the same system himself, especially during the past few years. Had he done so, he would not recommend a plan which, in its working, is nasty, mean and derogatory, and also a great barrier to the obtaining of good teachers. All teachers in the country are opposed to it, considering it most debasing in principle. Would our professors in Bloomsbury Square, or any other good teacher, like to be paid according to the results of the examinations? Ask any one also if the system of "coaching up" a student which is adopted by a teacher receiving payments on results is to be recommended. I would vastly like to ask Dr. Frankland if he would submit to this system which has been imposed upon others by the system of science teaching, in the management of which he has had a part. Certainly, examination papers have been framed to match the amount of money in hand; and what was seen twelve months since? Science teachers and students all dissatisfied. What do we behold now? The tumbling down of this system; the best teachers gone, having become disgusted with it; and perhaps one-sixth of the number of science teachers and students now that there were last year. Dr. Frankland, however, may not be to blame for this, having perhaps been obliged "to put on the screw" in order to comply with the "regulations" of our present Government.

The question of Provincial Education has many difficulties. Professors Redwood, Attfield, and Bentley may be able to give us some new information. May I propose that they each be invited to read a paper upon it at some evening meeting?

A Country Major Associate.

The Preliminary Examination.

Sir,—The letter in your Journal of May 25th, signed "Another who failed on April 8th," must surely be intended for satire, as it is scarcely credible that any one would seriously own to such dense ignorance. What a libel on the 21 young men at Manchester! No knowledge of the elements of arithmetic at Manchester of all places in the world! The 21 will, doubtless, in your next issue repudiate the base calumny. I had hoped in this age of education to sleep quietly in my grave, but the dreadful confession of your correspondent so troubled me that I could no longer rest. Hoping that I may not be so disturbed again,

The Shade of Cocker.

Sir,—I have read with great interest and pleasure the letter signed "One who has known the drug trade more than thirty years," and with one important exception I quite agree with what he has written. Until pharmacists set themselves determinedly against binding youths before they have passed the Preliminary examination, I consider it vain to expect apprentices to show much improvement. The youth he speaks of, who from his previous training ought to have been, and probably was, able to have gone up direct from school and passed his Preliminary, is, after two years, thought unable to do it; for carelessness and indifference have set in, and such a youth, knowing that he can have a reprieve for four or five years, makes no proper effort to keep up his knowledge. Had he passed before he was bound what energy he possessed would have been available for obtaining a practical knowledge of his business, and by the time his apprenticeship expired, he should have been able to pass his Minor examination.

One who has known the Drug Trade More than Forty Years.

Pharmaceutical Mnemonics.

Sir,—I wonder whether your ingenious correspondent, 'S. F. E.' has come across the following form for conf. sennæ.

"Coriander, tamarinds,
Senna, prunes and sugar refined;
Water, figs and cassia nice,
Made into a mass with liquorice."

Or, as to Sassafras:

"Pray, Mr. Sassafras, where will you go?
Into Decoctum Sarsæ co.?"

If not, I am pleased to introduce them to his notice.

J. Burt.

Worthing, June 1st, 1872.

E. W. Howe.—We are unable to give insertion to your letter.

S. N.—You cannot do better than follow one of the works mentioned in the official announcement respecting the prize.

"*Apprentice.*"—You should apply at Apothecaries' Hall.

G.—No. 2.

J. Wright.—We believe the excise authorities do not construe the Act strictly in reference to such a label as that sent by you. It would, however, be safer to apply at Somerset House.

J. H. D. Jenkinson is thanked for his communication.

"*Veritas.*"—The President desires us to refer *Veritas* to the rule as to anonymous communications.

"*Law.*"—Your question is a legal one; and without knowledge of the special circumstances, we hesitate to express an opinion.

R. J. M.—Medicated pessaries are generally made to weigh two drachms each; and when moulded in proper moulds, they have the shape of a rifle bullet, but broader. They may be prepared with oil of theobroma as a basis, although those containing salts like bromide of potassium, would be better prepared with a material made according to the formula given at p. 446 of the first volume of the present series of this Journal. This question was received too late to be answered in last week's Journal.

J. E. R.—The prescription sent (a formula which Mr. Erasmus Wilson often prescribes) makes a mixture of a clear sap-green colour. It is best prepared by rubbing the citrate, acid, and syrup together until dissolved, then adding the tincture, etc. Tincture of orange, varies very much in colour: if prepared from good dried thin English peel, it will be of a pale sherry colour. This may partly account for the difference you mention.

J. E. Lord.—According to your request we have submitted your letter to Mr. Joseph Ince, and you will find his reply printed on the previous page.

"*Victim.*"—We do not think there would be any difficulty in inserting such an advertisement as that you refer to, if forwarded to the proper quarter.

H. Sagar.—The article referred to has been stated by two or three respectable authorities to be a narcotic, and until this is disproved, we do not see that the conjectures put forth by you affect the question.

Communications, Letters, etc., have been received from Mr. P. Bedford, Mr. Rimmington, Mr. Henty, Mr. Druce.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 1006.)

KRAMERIÆ RADIX.—The toughness of this root causes it to be somewhat difficult to make a perfect section without very prolonged soaking in warm water. Cross sections may be very rapidly prepared for examination or permanent mounting in the following manner:—Having cut the sections as thinly as possible, place them in a watch-glass containing alcohol for a few minutes; remove them to a glass slip with plenty of alcohol, and cause the alcohol to boil for a few seconds, a thin cover having been placed upon the section to prevent its curling; remove the alcohol with blotting-paper, and add ol. anisi. Cause this to boil for a few seconds and remove as before. Add dammar or balsam dissolved in benzole, or dammar dissolved in ol. anisi, and when set, the object is ready for the cabinet. This method secures a great amount of transparency in certain dense tissues, such as can hardly be obtained in any other way, but it is obviously inapplicable to soft or delicate structures, or those in which delicate markings exist.* In the study of hard woods it is desirable that sections thus mounted should be carefully compared with those mounted in fluid or glycerine jelly, as these several media bring out different details into prominence.

In Krameria the medulla is insignificant, the appearance which a cursory inspection with the naked eye would lead us to infer was the medulla well developed being due to the presence of colouring matter in the older wood layers.

Wood Zone.—The structure of the wood zone is very interesting, whether viewed in cross section or studied more carefully in longitudinal section. The medullary rays are not very apparent in cross section, and in fact do not always extend beyond the earlier layers. They are somewhat short, sub-cylindrical cells, frequently very highly coloured, especially near the centre of the stem. They are very numerous, the incomplete vascular wedges of the wood being in consequence extremely narrow in proportion to their length. The highly coloured cells of the medullary ray contain but little if any starch; the uncoloured ones, however, contain a considerable quantity. This is particularly the case with the incomplete medullary rays (those which only extend part of the way across the stem, as from the bark to the middle layer, or from the centre to the middle). Seen in cross section, the wood cells are nearly circular, with considerably thickened walls. Vessels from two to four times the diameter of the wood cells are very numerous, and irregularly distributed among the wood cells. The boundaries of each year's growth are frequently well marked by difference of colour, this being greatly the case with the first and following year. The vessels are much pitted, the pores traversing the secondary deposits being well seen in longitudinal section. The pits are oval, disposed towards circular, and transversal. I have not been able to satisfy myself as to the existence of a spiral deposit in any of these vessels or in the wood cells, but there are traces which lead me to suspect its presence. In length the vessels exceed the wood fibres from two to four times, but are of very similar shape. The wood cells are peculiarly shaped, and resemble the cells of the "leaf" of sphagnum (sufficiently familiar as a show object to most microscopists) when seen in longitudinal section, intermixed with the cells forming the vessels. The wood cells are many times longer than they are broad, and are devoid of contents other than reddish-brown colouring matter. There are no raphides in any part of the root.

Cortical Zone.—The cortical layers comprise the usual layers of the bark, liber cells, and laticiferous vessels, the whole of which may be best studied in longitudinal section, beginning from the outside. The cells of the external layer do not require special note, being wholly of the usual type. Immediately below this is a layer of loosely aggregated, nearly globular parenchymatous cells, containing a richly coloured semi-fluid matter. The remaining layers are loose parenchyma cells, with the usual type of anastomosed laticiferous vessels and liber cells. The cortical layers are moderately rich in starch. The starch granules are round, with a somewhat indistinct hilum, of medium size, and less variable than usual. They give the usual cross with polarized light. No adulterations of powdered rhatany root are known to me. They would be easily detected by one familiar with the structure of the genuine root.

(*To be continued.*)

* Dammar dissolved in equal parts of ol. anisi and benzole sets more rapidly, a matter of importance to many.

STUDY.

BY W. WILLMOTT.

If I were to adopt the primary idea suggested by my title, I should commence at once an investigation into the laws of mind. From thence I should travel into the regions of matter; from thence to mind again, and from mind and mind's complexity to the unknown depths of metaphysical causality. Nor would it in any way add to my position to know, that from these unknown depths, after a presumably laborious research, I should emerge with but little real enlightenment on the subject of my inquiry; so intimate and so marvellous is the connection between mind and matter that it is impossible to determine where the influence of the one ends, and the other begins. I say this with all due deference to those eminent psychologists, Brown and Locke, who have expatiated so profoundly on mental and psychical philosophy. Even in the productions of these great writers there is abundant evidence of the inaptitude of the human mind to lift the veil from the attributes of the Infinite. From their perusal, therefore, we rise with a deepened conviction of man's inability to attain the summit of intellectual ambition. And if such is the case with the highest order of minds, still less, on an occasion like the present, can my remarks be consistently prefaced with any such attempt. I shall, therefore, simply premise that *mind* is the term by which we express the collective faculties of the brain; the brain being the organ through and by which the mind developes its nature and manifests its power. Some have told us that matter itself thinks, and that the continuance of matter in a peculiar form is essential to the perpetuity of consciousness. But were we to lay bare the brain with the hope of discovering these particles of thought, our labour would undoubtedly result in complete failure. Mind *per se* is immaterial, and therefore beyond the reach of anatomical research.

But I pass on to the consideration of my subject in a manner at once trite and practical. Lord Brougham says,—"He, who, in whatever station his lot may be cast, prefers the refined and elevating pleasures of knowledge to the low gratification of the senses, richly deserves the name of a philosopher." We might object here to the term "philosopher," because it is one which admits of very wide signification. The meaning, however, is sufficiently apparent as distinguishing those who are seekers after knowledge from those who prefer in its place the low gratification of the senses. A true philosopher must not only have knowledge, he must have *wisdom* to guide him in its application. The mere reading of books will never make us philosophers. Books, however, cannot be too highly prized as aids to knowledge and goodness; but withal there are so many of various kinds issuing from the press daily—I may say almost hourly—and so many ways of reading them when they come into our possession, that it is quite possible to wade through a mass of miscellaneous literature without a single accession to previous acquirement either in one direction or the other. That there is a good and a bad method in the matter of reading, there cannot be a doubt. By the adoption of the former we shall obtain great profit, but by the latter no profit at all. Some readers seem to delight in the number of pages they can turn over in a given time, whilst the majority too frequently ignore the very portion of a book which should first claim their attention, namely, the preface. The preface is, or ought to be, the key to the entire volume, and should never be passed over. Nor should the reader begin (as I regret to say I have seen some do) at the end of a book and read backwards—a little here and a little there — denouncing it as "dry" should he happen in his cursory examinations to stumble over a few sterling passages. No! if we wish to profit by our reading, we must read consecutively and by system, with due care and thought, always remembering the injunction of Lord Bacon, "not to believe and take for granted, but to weigh and consider." It should be borne in mind that knowledge is not gained by the quantity we read, but by the quantity we digest and remember. It is with the mind as with the body. The body is not sustained by the quantity of food we take, but by that which we assimilate. Therefore I say it is far better to read one page, or one book, carefully and well, than a hundred in a desultory and unprofitable manner.

But I desire here to distinguish between reading and study. Study is something more than the reflection on the brain of a succession of verbal ideas. It is that condensation of aggregate faculty, that power of abstract thought, that concentration of judgment and purpose, which carries the student, as it were, out of himself, and grapples successfully with the subject he aspires to conquer. This, I think, is study as distinguished from mere reading; and I would commend the inference to the earnest consideration of those who aspire to fame and distinction in the character of authors. There are so many questionable works constantly issuing from the press in conjunction with those of a really elevating character, that it requires considerable discrimination to choose between them. And this would seem to obtain in whatever department of literature we roam, though it must be said that works of fiction are especially open to the charge. A good book is a real friend, whilst a worthless one is a real enemy. Wordsworth has thus sung the praise of books:—

> "Books, we know,
> Are a substantial world both pure and good,
> Round which, with tendrils strong as flesh and blood,
> Our pastime and our happiness will grow."

I have nothing to say against works of fiction, provided they are really good; on the contrary, to those who cannot concentrate their attention on deeper themes they form a pleasing, and occasionally an instructive pastime. But works of fiction must always occupy a subordinate position on the shelves of the student. I do not mean the *sham* student, but he who loves knowledge for its own sake. He, indeed, is constantly reminded that he must not only read, but *study*,—that he must still go on, though the page were never so dry and wearisome. Happily, however, the struggle is progressive; for even while the oil flickers in the lamp, even while he stretches every thought and purpose toward victory, the clouds gradually disperse, the morning breaks upon him, and the glorious rays of an intellectual luminary brighten his onward course!

If I were asked to name the order of importance of the various branches of knowledge, I would decidedly rank science and philosophy before ordinary literature, and ordinary literature before those productions of which the element of imagination forms so large a component.* These, again, would precede that numerous class of works the perusal of which is so apt to inspire us with erroneous impressions both of men and things, and thus to sow in the mind the seeds of disappointment and regret. The languages are good exercise, and form ample ground for systematic reading; but to those who are just commencing life I would recommend as well the study of appropriately-written physiology and moral philosophy.† There are few studies more important than these; and yet, practically, there are few which are more generally neglected. The former teaches us the adoption of principles and practices having special reference to the laws of health, and the latter the regulation of faculty, sentiment, and propensity, and the application of those high moral and psychical influences which govern our whole being and make us what we are. In other words, the one has reference to our physical well-being, and the other

* "The first subject of study," said Viscount Palmerston, speaking of the sciences, in his address as Lord Rector of the University of Glasgow in 1863, "would naturally be that which is commonly comprised in the single term chemistry,—the operations of nature in all those elements in which we live and deal,—a knowledge of which is useful to every man in his individual condition, and on the study of which depends the industry, wealth and prosperity of nations. It is not to be expected that those who are destined for the church or the bar, or other such professions, should become skilful as analytical chemists; but they should be acquainted with the general principles by which substances act on each other, and this knowledge will be found useful in every position in life. Now, they concern the peasant in his cottage, the workman in his convenient dwelling, as much as they concern the great manufacturer in the arrangement of his business, because health and life are essentially connected with the practice, and the experience, and the counsel of the chemist."

† "Philosophy means literally the love of wisdom. It is the love of a hidden treasure; therefore it comes to mean a search after wisdom."—*Moral and Metaphysical Philosophy*, by Professor Maurice.

to our moral and intellectual well-doing. If young men (and, in this age of feminine progress, may I not also say young women?—the former with their generous hearts and lofty aspirations, and the latter with their bright hopes and cheering smiles) would devote only one hour in the day to these two subjects, and apply the facts so acquired to their every-day lives, I do not hesitate to affirm that a vast amount of sorrow and regret would be saved to the world; or would they devote this one hour to some other study of a useful and ennobling character, sure I am that, although they may not acquire the genius or the intellect of a Shakspeare or a Milton, a Butler, a Paley, or a Faraday, their minds would be expanded and improved, to their own good, both in time present and to come.*

One hour in the day is not a large demand; and I trust I shall not be thought severe when I say that in many instances young ladies may spare this small division of time from their conversations on the opera or the last new novel, or from their elaborate and self-imposed duties at the shrine of beauty and adornment; whilst, on the other hand, the same brief period may not unfrequently be subtracted by the younger members of the opposite sex from their fervent disquisitions upon political routine, or from those images of objects which float noiselessly away on the ridges of clouds blown from their favourite Havannah. But then it is so *hard* to study for oneself, and so *easy* to borrow one's neighbour's head; so hard to think, reflect, compare, compound, and abstract, and so easy to criticize, imagine and declaim. Yes; but it is just because this *is* so that study claims our acknowledgment. It tells us that if we will accept it as a friend, it will not betray our confidence; for, in addition to giving us an insight into action and passion, and leading us onward and upward, it will show us many marvellous things. It will show us what the world is in which we live, from those laws which govern the rolling of the mighty deep to those which preside over the smallest occurrences of ordinary life, both alike leading the mind by an unbroken chain from the material to the immaterial, from the finite to the infinite.

(*To be continued.*)

IODIDE AND BROMIDE OF POTASSIUM.

BY CHAS. D. CHASE.

The object of this note, as will be seen, is simply to call the attention of dispensers to the fact that most of the iodide and bromide of potassium found in the United States market, instead of being neutral, are alkaline in their reactions, and to illustrate the importance of this fact being generally known.†

The following prescription was prepared, with results as given below:—

℞. Morph. Sulph.	gr.iv	
Aquæ Cinnam.	℥ij	
Potass. Bromid.	ʒiij	
Syr. Tolut.	℥iss	
Elix. Calisayæ	ʒiv.	M.

The morph. sulph. was weighed and introduced into a four-ounce vial, the potass. bromid. weighed and rubbed in a mortar with the aqua cinnam. until entirely dissolved, and the solution poured over the morph. sulph. contained in the vial. The morph. sulph. refusing to dissolve after shaking, the vial was set aside and the preparation begun anew.

This time the morph. sulph. was dissolved in the elix. calisayæ, the potass. bromid. in the aqua cinnam., and the two solutions mixed.

A precipitate immediately followed, which, upon the addition of the syr. tolut., and after shaking, slowly arose to the surface of the mixture.

The preparation not being entirely satisfactory, a few experiments were made with a view of ascertaining the cause of precipitation. To be assured that the fault was not with the aqua cinnam. (which had been made by distillation from the bark), the prescribed quantity each of morph. sulph. and potass. bromid. was dissolved separately in distilled water, and the two solutions mixed.

The same result was obtained as when aqua cinnam. was used as the solvent.

An examination was next made of the morph. sulph., which proved to be pure sulphate of morphia. The chances for the potass. brom. to prove perfectly faultless now looked rather "slim." A solution of the suspected salt was made in distilled water, and tested with litmus and turmeric paper. The solution gave with both papers a decided alkaline reaction, which fact solved the mystery of the precipitation; for, as is well known, the alkalies and their carbonates precipitate morphia from solutions of its salts; and when the morph. sulph. solution came in contact with the free alkali (potassa) contained in the potass. bromid. solution, the precipitate must inevitably have taken place.

Several samples each of iodide and bromide of potassium were tested with turmeric paper, and in every instance the same alkaline reaction was observed.

The foregoing serves to show how serious accidents might occur by dispensing the salts of morphia (or other alkaloids) with iodide or bromide of potassium which gives an alkaline reaction; for if prescribed with syrup, as in the above prescription, the precipitated morphia will rise to the surface of the mixture, and, should it not be "shaken before taken," the patient will be liable to take all, or nearly all, the morphine in the mixture at a single dose.

It is therefore advisable for the dispenser, whenever a morphia salt is prescribed with iodide or bromide of potassium in solution, to first dissolve the latter, test the solution with turmeric or red litmus paper, and if alkaline neutralize with dilute muriatic acid before adding the morphia salt; and a bottle of the acid mentioned and the necessary test paper

* "The value of odd moments is incredible to those who waste them. An hour in every day withdrawn from frivolous pursuits and profitably employed, would enable a person of ordinary capacity to go far towards mastering a complete science. It would make an ignorant man a well-informed man in ten years. . . . . . Even fifteen minutes a day devoted to self-improvement will be felt at the end of the year."—*The True Road to Success.*

† The presence of alkaline carbonate in iodide and bromide of potassium is an impurity arising probably from the process of manufacture adopted in the United States. The reports on the iodide and bromide of potassium, used in medicine, published some two years since in the 'British Medical Journal,' show that in this country these salts are practically quite pure. See Vol. I. of the present series of the Journal, pp. 89 and 147.

should be placed convenient to the prescription counter, for this if for no other purpose.*

With a small proportion of morphia salt the precipitate is often not observed until after standing a short time.—*American Journal of Pharmacy.*

POPPY CULTURE IN AUSTRALIA.

Some attention has recently been given to the cultivation of the poppy for commercial purposes in various parts of Australia. From a letter which recently appeared in a colonial paper, describing the results of an experiment in poppy culture in the Bendigo district, we gather the following interesting facts. About a drachm of the seed, which was that of the white variety, was sown in the early part of August along each of three drills, 86 feet long and 2 feet apart, and were lightly covered with small firewood, bark and sand. The land was rather heavy, and mixed with a good deal of quartz. It had been well manured and broken up; grape vines had been grown on it for a succession of years. On the 18th day after sowing, the young shoots were visible, looking like fine blades of grass, and they continued to grow pretty well. When between five and six inches high they were weeded out, and several were transplanted, but all the latter died, in consequence, probably, of insufficient watering and the heat of the weather. By the 20th November the others were flourishing "like great cabbages." These began to flower pretty freely by the first week in December, by the time the plants were about 5 feet or 5 feet 8 inches high. The capsules produced varied in size from 1 inch to 2½ inches in diameter. After the petals had fallen off, and while the stamens were still clustering round the neck of the capsules, horizontal incisions half round the heads at their lower part were made. A creamy juice exuded from these cuts, which were made in the afternoon, and it soon became pinkish, and by the following morning brownish-red, and of a tenacious consistence, when it was scraped off with a sharp straight knife, and collected on the edge of a small tin cover, which plan is recommended as being less troublesome and not so wasteful as the usual one of gathering the opium upon the poppy leaf. Each poppy head did not yield more than equal to the bulk of a small pea, and from all the plants raised from the drachm of seed 250 grains of opium were collected; but it must be borne in mind that many plants were entirely lost, and others not matured. The opium collected was considered to be of very good quality.

The conclusions arrived at from this experiment are that the poppy requires a certain amount of careful nursing and a pretty liberal supply of water. The distance between the rows should be three feet, to allow of the full growth of the leaves and room to pass between the plants when collecting the juice. A sheltered aspect should be chosen, so as to protect the plants from strong winds. Finally, the writer says,—"The collection of the product is not, to say the least, very agreeable; and, from the length of time occupied by it, the labour must be very cheap for the crop to pay. Perhaps the plant might be cultivated with profit near industrial schools. In conclusion, I think the opium poppy can be successfully raised in this district if a plentiful supply of water be available when necessary."

---

* Commercial iodide of potassium is usually crystallized from alkaline solutions in order to obtain it in opaque cubes; recrystallization or granulation from water will effectually remove any adhering alkaline carbonate.—*Editor Amer. Journ. Pharm.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Zinci Acetas.—$Zn\ (C_2H_3O_2)_2\ 2H_2O$. Carbonate of zinc is dissolved in acetic acid diluted with about an equal quantity of water, and the solution set aside to crystallize,

$$ZnCO_3 . 2Zn\ (HO)_2 + 6\,[HC_2H_3O_2] = 3\,[Zn(C_2H_3O_2)_2] + CO_2 + 5H_2O.$$

The same compound is of course produced when the oxide or metallic zinc is dissolved in acetic acid. In the latter case hydrogen gas is slowly evolved.

The salt is recognized as an acetate by evolving acetic acid when decomposed by sulphuric acid, and as a compound of zinc by giving a white precipitate of sulphide of zinc with sulphuretted hydrogen or with sulphydrate of ammonium.

[§ A dilute watery solution is not affected by chloride of barium or nitrate of silver, and when slightly acidulated with hydrochloric acid is not precipitated by sulphuretted hydrogen; after it has been boiled with a little nitric acid, it yields with ammonia a white precipitate entirely soluble without colour in an excess of the reagent.] The foregoing tests taken in order are intended to indicate the absence of the following impurities:—Sulphate; chloride; copper and lead; iron.

Zinci Carbonas.—$ZnCO_3\ 2Zn(HO)_2 . H_2O$. Boiling solutions of sulphate of zinc and carbonate of sodium are mixed, and the liquid kept hot until effervescence has ceased. The precipitate is then collected and washed to free it from sulphate of sodium.

The carbonate of zinc which is at first precipitated is resolved by the action of water into CO_2, which escapes and a hydrate-carbonate which constitutes the official salt.

$$\begin{aligned} & 3ZnSO_4 + 3Na_2CO_3 + 2H_2O \\ = \; & 3ZnCO_3 + 3Na_2SO_4 + 2H_2O \\ = \; & ZnCO_3 . 2Zn(HO)_2 + 3Na_2SO_4 + 2CO_2. \end{aligned}$$

This decomposition of the precipitated normal carbonate in presence of water always occurs, except in the case of the barium, strontium, and calcium carbonates. [See Magn. et Ferri Carbonates.]

Zinci Chloridum.—$ZnCl_2$. Metallic zinc is dissolved to saturation in diluted hydrochloric acid.

$$Zn + 2HCl = H_2 + ZnCl_2.$$

And then in order to remove lead and iron, if present, from the filtered solution, a small quantity of chlorine water is added, and the whole is agitated with carbonate of zinc. The chlorine converts the metals into perchlorides.

$$\begin{aligned} 2FeCl_2 + Cl_2 &= Fe_2Cl_6 \\ PbCl_2 + Cl_2 &= PbCl_4, \end{aligned}$$

and the carbonate of zinc causes their precipitation as hydrates.

$$Fe_2Cl_6 + 3ZnCO_3 + 3H_2O = Fe_2(HO)_6 + 3ZnCl_2 + 3CO_2$$
and
$$PbCl_4 + 2ZnCO_3 + 2H_2O = Pb(HO)_4 + 2ZnCl_2 + 2CO_2.$$

By digesting the solution on an excess of metallic zinc, as the Pharmacopœia directs, no lead will be taken up.

Evaporated until watery vapour ceases to be evolved the solution leaves the zinc chloride as a colourless syrup, which solidifies on cooling. It may be made to crystallize from a very concentrated solution.

[§ Colourless opaque rods or tablets very deliquescent and caustic, soluble almost entirely in water, alcohol and ether.]

The white flocculent precipitate generally left when chloride of zinc is dissolved in water is oxychloride. For the detection of impurities the same tests may be employed as with the other salts of zinc.

Chloride of zinc enters into direct combination with ammonia, NH_3 and also with alkaline chlorides.

Zinci Oxidum.—ZnO. Carbonate of zinc is heated to redness in a crucible. Carbonic anhydride and water escape, leaving the oxide.

$$ZnCO_3\ 2Zn(HO)_2H_2O = 3ZnO + CO_2 + 3H_2O.$$

Oxide of zinc is deep yellow whilst hot, but becomes nearly white on cooling. It is sometimes made by submitting the metal to distillation in a current of air. The oxide thus obtained is very pure, but liable to contain particles of metal.

Zinci Sulphas.—$ZnSO_4 . 7H_2O$. Zinc is dissolved in diluted sulphuric acid, and when the acid is saturated, the solution is treated with chlorine and carbonate of zinc for the purpose of removing iron. A small quantity of chloride of zinc is thus introduced into the solution, but it is too minute to interfere with the purity of the crystals which are obtained on evaporation.

$$2FeSO_4 + Cl_2 + ZnCO_3 . 2Zn(HO)_2 . H_2O = Fe_2(HO)_6 + ZnCl_2 + 2ZnSO_4 + CO_2.$$

Sulphate of zinc is isomorphous with and closely resembles sulphate of magnesium. From that salt it is readily distinguished by giving white precipitates with ferrocyanide of potassium and sulphide of ammonium.

Sulphate of zinc is soluble in about two and a half times its weight of water; the solution has an acid reaction. The crystals lose six molecules of water by the heat of a water-bath, but, like the other sulphates of the same class, it retains the seventh molecule even at much higher temperatures. Impurities would be detected by the tests already given. [Zinci Acet.]

PREPARATION OF A VERY ACTIVE CANTHARIDAL PLASTER.

BY PROF. G. DRAGENDORFF (Dorpat, Russia).

Apothecaries frequently complain that some cantharides do not furnish an active blistering plaster; that the same furnish, even when treated with acetic ether, an extract so poor in cantharidin, that with its aid no good Drouott's blistering tissue can be produced. In most cases the opinion is expressed that the flies contain too small a percentage of cantharidin. My experience teaches me to discredit the latter opinion. It is possible to obtain good preparations even from such apparently poor cantharides, it being only necessary to thoroughly extract the cantharidin they contain.

A few observations show how poorly this is commonly accomplished. According to my experience the amount of cantharidin in Spanish flies varies from 0·27 to 0·5 per cent. The coating of a vesicating tissue 20 c. m. long and twelve wide requires about 25 grm. plaster substance, containing usually about 6 grm. powdered Spanish flies, furnishing at least 0·016 cantharidin. 0·00002 grm. cantharidin suffice for a blistering surface of a square centimeter, or 0·0048 grm. for 240 square centimetres, or less than one-third of the smallest quantity that may be considered present in the plaster. Mechanical causes may partly be found to be the ones that prevent a thorough action of the plaster. A plaster of poor adhesiveness, not being in close contact with the epidermis, does not act because that close contact is wanting, which is necessary for the absorption of the cantharidin. It is also a mistake of several pharmacopœias to permit the use of coarsely-powdered cantharides, the quantity of cantharidin in which is not uniformly distributed in the plaster, even if the powder is heated for a long time with the oil.

Other causes, unnoticed heretofore, also weigh heavily in this direction. The cantharidin is present in the Spanish flies in several different combinations, in which it is firmly held. This fact I have mentioned already in my "Contributions to Toxicological Chemistry," on the different behaviour of flies towards various solvents. Cantharides with about 0·3 per cent. of cantharidin yield to water, even after repeated boiling with fresh portions of the same, only about half of their cantharidin, while the remainder is only yielded to potassa lye. In the same manner, alcohol, chloroform, and ether dissolve only 30 per cent. of the blistering substance. If all the cantharidin is to be extracted, bases like potassa or soda must be employed, which form easily soluble salts with the cantharidin. Together with Masing, I demonstrated years ago that the salts thus formed are energetic blistering agents. During the past two years, reference has occasionally been made to our observation, especially by Delpech and Guichard, recommending the cantharidates of soda and potassa as vesicants.

Without alluding to this further, I would say that by the aid of soda or pottassa the entire amount of cantharidin contained in the flies may be rendered active. The finely-powdered flies are mixed to a paste with diluted alkaline lye of about 1·1 sp. gr., heated in water-bath for twenty-five to thirty minutes, when sufficient muriatic acid is added, to have a trifling surplus of the same, and the whole mass is dried rapidly in the water-bath. The residue, which we may call "prepared cantharides," is powdered anew and employed for the preparation of the plaster, or for the extract with acetic ether for use upon tissue. The small quantity of potassium or sodium chloride present, is in no case injurious. The cantharidin is now present in the mixture in a free state. In a drug store in this city, where my proposition has been followed, no complaints have been made about the preparation.

Even for the preparation of the pure cantharidin, the above-mentioned process is worthy of attention. As I mentioned before, ether, alcohol, etc., dissolves from the cantharides, not "prepared," only a fraction of the cantharidin present.—*The Chicago Pharmacist.*

DISTRIBUTION OF ATROPINE IN THE LEAVES AND ROOTS OF THE BELLADONNA.

BY M. LEFORT.*

Therapeutists have been long divided in opinion as to the relative degree of activity of the parts of the belladonna plant most used in medicine, namely, the leaf

* Memoir read before the Paris Academy of Medicine, Nov. 21, 1872 (Journ. de Pharm. et de Chimie [4] vol. xv. p. 265.

and the root. Whilst according to the experiments of some authors, equal doses of the leaf and the root have appeared to possess properties absolutely identical, the experience of other observers has led them to consider the root to be more active and generally more constant in its results than the leaf.

In seeking for the origin of this divergence of opinion some points must be considered to which it is probably to be attributed: (1) the different times of the year at which the leaf and root are collected; (2) the great influence the age of the plant has upon the formation of atropine; and (3) the notable difference in composition between the cultivated plant and that growing wild or in the woods. It appeared to the author that well-directed laboratory experiments would best solve these questions, and he, therefore, undertook a great number of very minute analyses, the results of which are given in the present memoir.

1. *General Method of Analysis.*

Reviewed in a general aspect the dry belladonna leaf is composed of cellulose, chlorophyll, a salt of atropine, a nauseous poisonous principle, and a fatty or waxy substance characteristic of all vegetables. The root, on the contrary, is principally represented by cellulose, starch, inuline, asparagine, the nauseous fatty matters and a salt of atropine.

Atropine having hitherto been considered the essential principle to which all parts of the belladonna plant owe their therapeutic and physiological properties, the best method of estimating that alkaloid was sought. In the first place recourse was had to tannin and iodide of potassium, which produce with atropine precipitates that are very insoluble in water; but in studying carefully the composition of these deposits, it was found that they contained foreign matters that could not be separated by washing.

MM. Winckler, Planta, Richenau and Mayer have pointed out that the double iodide of mercury and potassium, or iodhydrargyrate of potash, is the reagent that best precipitates the vegetable alkaloids from aqueous solutions in the presence of colouring and other matters existing in the plant. The experience of the author in the examination of decoctions of the leaves and roots of belladonna is confirmatory of the observations of those chemists, the solution employed by him in all his analyses being—

Corrosive Sublimate	4·50	grams.
Iodide of Potassium	16·25	"
Distilled Water	50·00	"

In order correctly to compare the quantities of iodhydrargyrate of atropine furnished by the leaves and roots in different stages of growth, the analyses were conducted under conditions absolutely identical in all cases. 100 grams of the root or leaf was reduced to an impalpable powder, and completely dried in a stove. It was then treated with lukewarm rectified spirit until exhausted of all principles soluble in that vehicle. The greater part of the spirit was then distilled off, the residue heated in a water-bath to drive off the last traces of alcohol, and sufficient distilled water added to make an aqueous solution of 50 c. c. To this solution, filtered, was added the solution of iodhydrargyrate of potassium in slight excess, and the precipitate of iodhydrargyrate of atropine so formed collected on a weighed filter washed, dried, and fused in a platinum capsule. On cooling, the product was hard, transparent, brown, undecomposed by air, insoluble in water, but very soluble in alcohol.

The quantity of pure atropine present was then easily calculated, theory giving the proportion of the alkaloid in 100 parts of the iodhydrargyrate as 33·25. The author considers this method of estimating the quantity of atropine far preferable to those based upon its production in the free state, since he has found that the alkaloid is always more or less altered by the chemical agents used for its isolation.

2. *Atropine in the Leaves.*

The author's attention was directed first to ascertaining the time of the year at which the leaves of the belladonna plant are usually collected, and he found that both from the wild and the cultivated plant the gathering takes place through the months of May and June on to the end of August;* that is to say before, during and after the flowering of the plant. The first question to decide, therefore, was whether the leaf collected in the spring was as rich in atropine as that collected in the middle or at the finish of the summer. Some leaves, therefore, were obtained that were gathered from plants cultivated in the neighbourhood of Paris in the month of May,—that is to say, before the flowering,—and another part gathered in August at the time the berries commence to ripen. These too kinds of leaves gave the following results:—

Atropine in 100 *grams of dry powder.*

Experiment.	May leaves. Gram.	August leaves. Gram.
1	0·418	0·457
2	0·405	0·443
3	0·421	0·467
4	0·392	0·482

These analyses show that the belladonna leaf is less rich in atropine in the spring than after the floral organs have faded. It is true that the difference is so slight that there would be some difficulty in distinguishing between the physiological action of the two kinds; but the author considers that if the collection were not to take place till July or August, the results would be a medicinal agent nearly invariable in composition and possessing the largest quantity of the active principle.

Another question not less important was to determine the influence that cultivation exercised upon the proportion of atropine. Towards the end of July, therefore, one portion of leaves was obtained from plants cultivated in the neighbournood of Paris, and another from wild plants growing in the forest of Compiégne. These yielded the following results:—

Atropine in 100 *grams of dry powder.*

Experiment.	Cultivated leaf. Gram.	Wild leaf. Gram.
1	0·470	0·459
2	0·485	0·47[illegible]

So that, from these analyses, it appears that cultivation neither lessens nor increases the quantity of atropine, and that the medical man may have equal confidence in the leaf from the cultivated and from the wild plant, provided they are gathered at the same season of the year.

The conclusions drawn from the experiments on this part of the subject are:—(1) that the belladonna leaf is less rich in atropine before than after the flowering of the plant; (2) that its collection should always be made between the flowering and fructification; and (3) that the leaf of the wild and the cultivated plant contain identically the same proportions of atropine when gathered at the same time of the year.

3. *Atropine in the Roots.*

It has previously been mentioned that, except in atropine, the composition of the leaf was far from resembling the root of the belladonna, and this is a fact important to be remembered when it is sought to compare

* Gonesse, Choisy-le-Roi and Orly are the principal localities in the environs of Paris where the belladonna is specially cultivated. The leaf is not generally collected until the second year of the plant's growth, and is continued during eight, ten, or even twelve years, according to the nature of the soil. The collection is made twice in the year: the first towards the end of May; the second in August, or at the end of July.

their physiological and therapeutic properties. In former experiments * the dried leaf was found to contain 3 per cent. of a fatty matter, coloured by chlorophyll, giving off strongly the odour peculiar to the poisonous *Solanaceæ;* the dried root does not contain more than 1 per cent. of this matter, coloured yellow, with an odour equally nauseous, but not so pronounced. The nature of this poisonous principle, and the part that it plays in the preparations which contain it, is a subject worthy of investigation. Without doubt, plants produce upon the animal economy physiological effects as much more decisive as their chemical composition is itself more pronounced; but it must not be forgotten that their special therapeutical properties are often as much due to the combined action of the constituent principles as to the predominance of one. So that, considering the difference existing in the composition of the belladonna leaf and the root, it is difficult to make a comparison between them as to their therapeutic action, and they should rather be looked upon as relatively than absolutely similar.

From the manner in which the plant is developed, there is great difficulty in fixing the time of the year when the atropine is present in the root in the largest proportion. It is well known that the belladonna plant forms each year one or more fresh roots that soon acquire considerable size, partly at the expense of the old ones, which are thus deprived of a portion of their atropine. As the belladonna plant lives at least from eight to twelve years, according to the nature of the soil, it follows that there is great variation in the composition of these roots.

In France the collection and selection of the roots are carried on by persons badly qualified for the work. The wild roots are gathered at any time; and, provided that they be not too spongy, are handed over just as they are to the dealer, who contents himself with cleaning them, splitting the larger roots to facilitate their drying. The cultivated roots are collected in an equally defective manner. When the plants are old, and produce few leaves, they are pulled up in order to replace them by new plants, and the portion of the roots that is not hollow is taken; so that the produce which comes into the hands of the druggist consists of roots of every size and age and extremely variable in the proportion of atropine they contain. Analyses of roots of different ages gave the following results:—

Atropine in 100 *grams of dried powder.*

Experiment.	Root 2 to 3 years old. Gram.	Root 7 to 8 years old. Gram.
1	0·4718	0·2541
2	0·4886	0·3128

These numbers show the mean result; since, while some roots contained less than three grams per kilogram, others contained more than five grams. One specimen, said to have come from the Swiss mountains, yielded nearly six grams, the largest proportion that was met with. This variation would seem to indicate that, with regard to the atropine, the leaf is more trustworthy than the root.

For a considerable time French manufacturers of atropine have preferred the German or Swiss roots to those collected in their own country. This preference the author considers, from experiments, to be due, not so much to the difference in the root, as to the care with which the collection is conducted. The belladonna root differs much from that of other herbaceous or perennial plants containing powerful alkaloids, such as henbane, stramonium, or aconite. In the aconite, for instance, M. Duquesnel has found † that the root contains more aconitine than the leaf; but whilst the aconite root does not grow much larger than the thumb, the belladonna root grows with such rapidity that it is not unfrequently met with as large as the arm. It is well known that in very large roots the cortical part is less abundant in proportion than in smaller roots. A kilogram of belladonna roots eight or nine years of age would contain about 300 grams of bark; the same weight of three-year old roots would contain about 400 grams. So that, as the bark, both of the root and the stem, always contains a larger proportion of the active principle than the medullary layers, this difference of 25 per cent. of bark in favour of young roots explains the foregoing results of analyses.

The principal conclusions drawn from this part of the investigation are:—(1) that in general composition the root differs notably from the leaf; (2) that the older the root is, the smaller the proportion of atropine that it contains; (3) that though the root is frequently richer in atropine than the leaf, the proportion is much more variable, and therefore the leaf would have more uniform therapeutic properties.

CHINESE CHEMICAL MANUFACTURES.*

BY F. PORTER SMITH, M.B.

(*Concluded from page* 1009.)

The ashes of Polygonum plants, forming a rough salt of potash, were formerly used as a flux for minerals, and as an addition to cane-juice to neutralize the acid present. This latter purpose is now fulfilled by using lime, a chemical substance formerly handled by experimenters. Sulphate of soda, named *Hieunming-fen* after *Liu Hieun-chin*, the Glauber of Chinese alchemy, who flourished during the reign of the second *T'ang* emperor, has received much attention at the hands of Chinese operators, who give minute and ridiculous directions for the purification of this salt, which is found as an efflorescence upon the ground of some parts of the country. It is, naturally enough, confounded with the natural nitrates of potash and soda so common in both China and India. It was anciently believed to be one of the substances capable of inducing longevity, and to be a panacea for most sicknesses. Sulphate of magnesia, or Epsom salts, is referred to in the *Pen Ts'au* as a "bitter nitre," prepared from the mother-liquor of the salt-pans. Judging from the deliquescent character of all the salt made or met with in China, the plan of removing this magnesian element from the crude salt is not practised at the present time. The phenomena of deflagration and crackling of salts of potash and soda are so frequently referred to in Chinese works as to lead us to believe that they practised something equivalent to our blowpipe examinations of substances. The use of fire to distinguish arsenical substances, such as black (metallic) arsenic, white arsenic (arsenious acid), and yellow arsenic (orpiment), as by the varying smell of these substances, indicates a step in the direction of practical chemistry. Passing on to alum, as the last of these alkalies, or alkaline earths, we touch upon an interesting subject. The making of alum, as at Wan-chau-fu in Chehkiang province, from the alum-shale of the hills of that prefecture, is an extensive business. The alum is exceedingly pure and exceedingly cheap. Its uses in sizing paper, in making mucilage, and in many chemical and economical processes are even less important than its employment day by day in the purification of drinking-water—a chemical operation. The Chinese formerly employed carbonate of soda for this purpose, thereby yielding a much softer water than the alum process does. The author of the *Pen Ts'au* curiously enough recommends the use of leaden vessels to hold water, liable to produce goitre.

* Reprinted from 'Transactions of the North China Branch of the Royal Asiatic Society.'

Metals have received much attention at the hands of the Chinese, who revel in alloys, and love the cheap thunder of gong-metal, and the musical ring of pieces of silver. Copper is regarded by Chinese writers as more friendly to the human constitution than iron, and they prefer the former metal for the making of cooking and washing vessels. Malachite is well known to them, and sulphate of copper, or *Shih-tan*, is described in their works, although never met with in Hankow. Steel needles dipped in a solution of sulphate of copper have been sometimes sold to foreigners as curiosities in the way of well-tempered metallic copper. Although aware of this decomposition of one metal by another, the Chinese have misunderstood it, and they have been led into the assertion that one metal undergoes conversion into the other. Verdigris, a basic acetate of copper, is easily procured by the action of vinegar on plates of copper. Vinegar is the only pure acid substance known to the Chinese. They use it as a solvent; and by sprinkling it upon minerals exposed to the fire, they bring about oxidation and solution of these substances. It is curious that they have never learnt to distil acetic acid from their strong but rank vinegar. Verditer, a carbonate of copper, is largely made by the Chinese in Hupeh, and is mixed with rice-starch for some reason best known to themselves. It occurs in small, thin, square, pale green pieces, and is used in dyeing shagreen cases for pipes and spectacles. There is a process described in a Chinese work by which wood to be placed in water is preserved by previously dressing it with acetate of copper solution. This is something like the Kyanizing process, in which corrosive sublimate is similarly employed. Iron, a metal abundantly bestowed upon China, yields oxides and the sulphate of iron in various forms. The black oxide of iron dissolved in vinegar was formerly employed by the Chinese as an ink. The characters were written with this solution, and the pencil, dipped in the ordinary Chinese or Indian ink, was used to trace over the characters on the other side. The red sesquioxide of iron is made on a large scale by heating impure sulphate of iron to a great heat. The hotter the fire the better the colour, so the *Pen Ts'au* says. This rouge is used to colour porcelain, and to redden walls of temples and palaces. Sulphate of iron is made in a crude and cheap form by mixing together sulphurous coal and hepatic iron pyrites, and covering the heap with mortar and mud to prevent the access of air. Spontaneous chemical action occurs, and the mass which results is treated with water, and the rough green salt is crystallized out. This is sold at a very cheap rate, and is much used as a dye, after mixture with galls or other substances. It makes a very good disinfectant for sewers, urinals and the night-stools of the sick-room. A preparation of great beauty, called *Tieh-hwa-fen*, is made by acting upon sheets of iron with vinegar. It resembles the citrate of iron in its appearance. The Chinese seem to be aware of some sort of identity of the colouring matter of the blood with these iron preparations recommended in diseases of the blood.

Lead is scarce in China, comparatively. It is spoken of as the "black metal," and is regarded as masculine, and the progenitor of the five principal metals. Lead, zinc, antimony and pewter are not carefully distinguished. There was formerly considerable communication between Persia and China. Persia sent lead, zinc, ores of silver and amalgams to China. Argentan, or German silver, called *Peh-t'ung*, is an alloy of copper, arsenic and zinc, largely prepared for use in making tobacco-pipes. The use of sal ammoniac as a test for these alloys, showing them to contain copper and to be not silver, is another item of chemistry met with in the *Pen Ts'au*, the manual of the Chinese chemical manufacturer. Acetate of lead is a salt much extolled by Taoist writers as a styptic remedy. A plan of making a salt, supposed to be an acetate, is given in the *Pen Ts'au*, by which an amalgam of fourteen parts of lead with one of mercury is acted upon by vinegar. This must issue in the formation of white lead, a salt made at many places in China, and largely used as a paint and as a face-powder. It would be curious if it should turn out, as may be expected, that an amalgam of lead and mercury, the latter being in very small proportion, is much more readily acted upon than the fine metal by vinegar. White lead was known in the days of the Great Yü, the engineer-monarch, and most certainly during the *Shang* dynasty. Shin-chau in western Hunan, and Kwang-sin-fu in Kiangsi, being both in the midst of rich mineral tracts of country, have been long famous for their chemicals. The most interesting and important substances of all are the mercurial preparations made for ages by the Chinese. Mercury, called "water silver," the exact equivalent of the Latin and Greek names for quicksilver, has had a mysterious attraction for the Chinese alchemists. Its liquid and volatile character, the beautiful colours of its compounds, and the powerful effect of its preparations, all tend to render it the hope of the chemist in search of omnipotent gold or immortal drug. Cinnabar, the most frequent ore of mercury, is also made artificially on a large scale in Hankow and other places, by fusing a mixture of sulphur (two catties) and mercury (one catty) and subliming it. To give a sample of Chinese philosophy, it may be observed that one author quoted in the *Pen Ts'au* says that by the absorption of the spermatic (or *Yang*) principle, a crude matrix is produced, which in a period of 200 years becomes pure cinnabar. This, in 200 years, becomes lead; in 200 years more it is silver, and in 200 years more of gestation it becomes pure gold. The nature of this sulphide of mercury was thoroughly understood by the early Chinese operators. The power of raising men to the rank of the eight jolly immortals called *Sien*, or "genii," was asserted of this mysterious substance, which defied heat and came forth a pure and mobile metal. They called it the *Sien-tan*, or "philosopher's stone," a name perhaps more properly assigned to a substance formed by the mixture of some eight substances. More than ten sorts of cinnabar are described in old works. That from Shin-chau-fu, in Hunan, has had the greatest reputation, and given its name to this chemical. Vermilion is made in much the same way in Hankow as the cinnabar which has the same chemical composition. The crystalline sublimate formed on the sides of the vessel is carefully powdered between two stones turned by the hand, a little water being added from time to time. The pasty mass is then carefully levigated by mixture with pure water, decanted, and dried upon tiles in the sun, in just the same way as described by Dr. Williams in his 'Chinese Commercial Guide.' The more patiently and carefully the cinnabar is powdered and washed, the finer is the colour of the resulting vermilion. It is packed in glazed black paper, and exported in large quantities. Æthiops mineral is a common drug, used in medicine as an alterative, and made by melting two Chinese ounces of sulphur and then adding to it half a catty of mercury. The mass is taken out, powdered and sublimed. It is sold in heavy, broken pieces, of a brilliant maroon or purplish-red colour, and crystalline or striated in structure. It corresponds exactly to the old officinal preparation of European Pharmacopœias. Calomel is made in large quantities in Hankow, in much the same way as that given by Mr. Pearson in the third volume of Sir J. Davis's work on 'The Chinese.' Common salt, mercury and alum, or salt, mercury, sulphate of iron and nitre are rubbed together in certain proportions, and put into an iron platter, which is covered over with a roomy earthen dish well luted down. This is exposed to the heat of a strong charcoal fire for four hours, when water is thrown upon the upper pan, and the removal of it shows the calomel condensed in the form of a beautiful, white, glistening, feathery sublimate upon the inner surface of the upper dish. It is the delicate appearance of this preparation which probably has induced the Chinese to call it the "light powder." It is often adulterated, as Mr. Daniel Hanbury has pointed out in his valuable Notes on Chinese Materia Medica,' with selenite, or sulphate of lime, which happens to be of nearly the same weight and crystalline form. There are some seven or eight manufacturers of this drug in Hankow. It sells at a price varying from sixpence to a shilling per ounce.

Corrosive sublimate, called literally "white precipitate," is also made in Hankow by a very complicated way, by fusing together nitre, mercury, borax, sal ammoniac, orpiment and massicot, and subliming the mass in the same way as the calomel. A very good crystalline preparation is obtained, which is used only externally as a caustic. The lead is added on medical, and not on chemical grounds, as it is supposed to correct the poison of the salt. Red precipitate is made by putting nitre into a small boiler and melting it, alum being afterwards melted and incorporated with it. Some mercury is put into the middle of the mass; and, after covering it over with a small dish, the whole is heated for about an hour and a half. The heat is at first gentle, and is then gradually increased. The red precipitate, or red oxide of mercury as it is, is taken out in the form of sublimated scales, of a bright brick-red colour. A nitrate of mercury, mixed with the red oxide, is sold under the same names as the red precipitate. A turbith mineral, or yellow sulphate of mercury, is also sometimes made by the Chinese.

Several metallic substances, such as minium and massicot, have been purposely passed over in this very brief and hurried sketch.

One more chemical substance, of an organic or animal character, shall be named as the last of this list. Urea, called *Ts'iu-shih*, is a regular article of manufacture from human urine at Ngan-king-fu and Chi-chau-fu, in Nganhwei province. This substance, mixed with the other constituents of the excretion, is obtained by boiling down urine, sulphate of lime or common salt being added to hasten the crystallization and to increase the quantity obtained. It is used to soften fresh meat required for immediate use, and is used in medicine.

Sufficient evidence, it is hoped, has been produced to show that there is such a thing as chemistry in China, and that those who take upon themselves to teach the Chinese chemistry would do well to first address themselves to the explanation of processes and terms already in the hands and mouths of the Chinese for many hundreds of years.

THE BARK OF JUGLANS CINEREA.

BY CHARLES O. THIEBAUD.*

A quantity of the fresh bark was gathered, carefully dried and powdered. From a portion of this a decoction was made, and the following reactions observed. No precipitate occurred after acidulation with nitric acid by iodo-hydrargyrate of potassium, thus proving the absence of an alkaloid. Dilute solutions were reddened upon the addition of an alkali. The vapour arising from both the decoction and aqueous extract gave acid indication to moistened litmus, the vapour from the extract turning it a decided cherry-red colour. A portion of the powdered bark, moistened with water slightly acidulated with sulphuric acid, and introduced into a retort, gave a straw-coloured distillate with a faint fusel oil odour, acid to litmus, and reddened by alkalies. This being made slightly alkaline by ammonia and set aside in a drying-closet, after evaporation to dryness, yielded a small quantity of slightly yellowish prismatic crystals, scarcely soluble in alcohol, and with acid reaction. The bark distilled with pure water gave a distillate with acid reaction, but deposited no crystals upon evaporation. The distillate obtained by treating the bark with water rendered slightly alkaline by carbonate of soda was neutral to test paper. These experiments prove a volatile acid to be present in the bark.

The decoction was treated by acetate of lead, the precipitate suspended in water, freed from lead by saturation with hydrosulphuric acid and filtration; the solution evaporated to dryness on a water-bath, exhausted by alcohol, and the alcoholic solution evaporated in the drying-closet to a resin-like extract. This was redissolved in alcohol, and set aside in a cool place. After a few days small acicular crystals were found floating on the liquid. These crystals were in small quantity colourless, and coloured litmus red.

The filtrate was freed from lead by hydrosulphuric acid, and evaporated to dryness on a water-bath; the residue, exhausted by alcohol and evaporated, yielded a bitter extract-like mass, soluble in both alcohol and water.

These results not proving satisfactory by the isolation of an acid in quantity sufficient for further examination, the peculiar solvent properties of true benzole were brought into requisition.

A portion of the freshly dried and powdered bark was macerated in this menstruum for four days. The benzole, which at first was colourless, after separation from the refuse matters by expression and filtration, was of a decided bright yellow colour. This was set aside and allowed to evaporate spontaneously. After the evaporation had been carried on until the residue ceased to lose weight, the capsule was found to contain a thick oily substance, and the sides were covered by short acicular crystals of a bright orange-yellow colour. These exhibited decided acid properties to litmus, were soluble in alcohol and ether, but scarcely so in water. They volatilized without fusing, in solution were reddened by ammonia, and turned pale violet by potassa, afterwards becoming red. The oily residue remaining after the evaporation of the benzole was exhausted with alcohol and the alcoholic solution by spontaneous evaporation yielded crystals similar in form, size and reaction to those deposited on the side of the capsule. The residue insoluble in alcohol was taken up by ether, allowed to evaporate spontaneously to a syrupy consistence, and spread on bibulous paper; thin tabular crystals were obtained which were colourless, acid to litmus, insoluble in water, scarcely so in alcohol, but readily taken up by ether, which solution was not precipitated by chloride of calcium and not affected in colour by ammonia or potassa. They were fusible, but being further heated partly volatilized, leaving behind a charred mass, which burned without residue. The crystals when fused were changed to a dark red liquid, which when treated by ether became decolorized.

Chrysophanic acid is soluble in benzole; and since from *Juglans*, by the use of the same solvent, a product is obtained which exhibits some of the characteristics of the former, we may regard the two acids as closely related. The proper name of this constituent would be juglandic acid.

Solution of sulphate and tincture chloride of iron produced dense dark-coloured precipitates, but other tests did not prove the presence of tannin.

The decoction affords precipitates, and hence is incompatible with the sesqui- and proto-salts of iron, bichromate of potassium, sulphate of copper, acetate of lead, and nitrate of silver. No effect is produced by yellow and red prussiates of potassium, tannin, and antimonial salts.

The bark contains bitter extractive, a large amount of oily matter, juglandic acid (which appears to be related to chrysophanic acid), an acid crystallizing in tabular colourless crystals, a volatile acid, and no tannin. The ashes were found to contain a considerable percentage of potassium, with traces of sodium, calcium, and aluminium.—*Amer. Journ. Pharm.*

THE TALLOW TREE AND ITS USES.

BY D. J. MACGOWAN, M.D.

The botanical characters of this member of the *Euphorbiaceæ* are too well known to require description; but hitherto no accurate account has been published of its various uses. Although it has become a common tree in some parts of India and America, its value is appreciated only in China, where alone its products are properly elaborated. Analytical chemistry shows animal tallow to consist of two proximate principles—stearine and elaine. Now, what renders the fruit of this tree peculiarly interesting is the fact that both these principles exist in it separately in nearly a pure state. Nor is the tree prized merely for the stearine and elaine it yields, though these products constitute its chief value; its leaves are employed as a black dye; its wood is hard and durable, and may be easily used for the blocks in printing Chinese books and various other articles; and, finally, the refuse of the nut serves for fuel and manure.

The *Stillingia Sebifera* or tallow-tree is chiefly cultivated in the provinces of Kiang-se, Kiang-nau and Chih-kiang. In some districts near Hang-chau the inhabitants defray all their taxes with its produce. It grows alike on low alluvial plains and on granite hills, on rich moulds on the margin of canals, and on the sandy sea-beach. The sandy estuary of Hang-chau yields little else. Some of the trees at this place are known to be several hundred years old, and, though prostrated, still send forth branches and bear fruit. Some are made to fall over rivulets, forming serviceable bridges. They are seldom planted where anything else can conveniently be cultivated, but generally in detached places, corners about houses, roads, canals, fields, etc.

In winter, when the nuts are ripe, they are cut off with the twigs by a sharp bill hook attached to the extremity of a long pole, which is held in the hand and pushed upwards against the twigs, removing at the same time such as are fruitless.

The harvesting accomplished, the capsules are taken and gently pounded in a mortar to loosen the seeds from their shells, from which they are separated by sifting. To facilitate the separation of the white sebaceous matter enveloping the seeds, they are steamed in tubs having convex, open wicker bottoms, and placed over cauldrons of boiling water. When thoroughly heated they are mashed in the mortar and then transferred to bamboo sieves, kept at a uniform temperature over hot ashes.

As a single operation does not suffice to deprive them of all their tallow, the steaming and sifting is therefore repeated. The article thus procured becomes a solid mass on falling through the sieve, and, to purify it, is melted and then formed into cakes for the press. These receive their form from bamboo hoops, a foot in diameter and three inches deep, which are laid on the ground over a little straw. On being filled with the hot liquid, the ends of the straw underneath are drawn up and spread over the top, and, when of sufficient consistence, are placed with their rings in the press. This apparatus, which is of the rudest description, is constructed of two large beams placed horizontally so as to form a trough capable of containing about fifty of the rings, with their sebaceous cakes. At one end it is closed, and at the other adapted for receiving wedges, which are successively driven into it by ponderous sledge hammers wielded by athletic men.

The tallow oozes in a melted state into a receptacle, where it cools. It is again melted and poured into tubs smeared with mud to prevent adhesion. It is now marketable in masses of about eighty pounds each, hard, brittle, white and opaque, tasteless, and without the odour of animal tallow. Under high pressure it scarcely stains bibulous paper; it melts at 104° Fahr. It may be regarded as nearly pure stearine; the slight difference is doubtless owing to the admixture of oil expressed from the seed in the process just described. The seeds yield about eight per cent. of tallow, which sells for about five cents per pound.

The process for pressing the oil, which is carried on at the same time, remains to be noticed. It is contained in the kernel of the nut; the sebaceous matter which lies between the shell and the husk having been removed in the manner described, the kernel and the husk covering it are ground between two stones, which are heated to prevent clogging from the sebaceous matter still adhering. The mass is then placed in a winnowing-machine precisely like those in use in western countries. The chaff being separated, the white oleaginous kernels are exposed, and, after being steamed, are placed in a mill to be mashed.

This machine is formed of a circular stone groove twelve feet in diameter, tapering at the edge, and is made to revolve perpendicularly by an ox harnessed to the outer end of its axle, the receiver turning in a pivot in the centre of the machine. Under this ponderous weight the seeds are reduced to a mealy state, steamed in tubs, formed into cakes and pressed by wedges in the manner before described, the process of mashing, steaming and pressing being likewise repeated with the kernels.

The kernels yield about thirty per cent. of oil. It is called *tsingyu*, and sells for about three cents per pound. It answers well for lamps, though inferior for this purpose to some other vegetable oils in use. It is also employed for various purposes in the arts, and has a place in the Chinese pharmacopœia, because of its quality of changing grey hair to black, and other imaginary virtues. The husk which envelopes the kernels and the shell which encloses them, and their sebaceous covering, are used to feed the furnaces; scarcely any other fuel is necessary for this purpose. The residuary tallow cakes are also employed for fuel; a small quantity of it remains ignited a whole day. It is in great demand for chafing-dishes during the cold season.

Finally, the cakes which remain after the oil has been pressed out, are much valued as a manure, particularly for tobacco fields, the soil of which is rapidly impoverished by that plant.—*Scientific American.*

NEW MATERIAL FOR BRICKS.

During the last few years experiments have from time to time been made with the view to utilize in some way the mounds of shale (the refuse of the coal mines) which cover an area of several thousands of acres in South Staffordshire by converting them into bricks. Several enterprising firms have already embarked in this novel but profitable business. When properly pulverized, the shale is found to be an excellent material for the purpose, the bricks produced being hard and durable, resembling in colour the fire-clay bricks of the Stourbridge district, although for furnace and such like purposes they are not so valuable. For ordinary building, however, they are found to be of equal practical value to the ordinary red bricks, the only possible objection to the former being their colour, which is somewhat too light for a smoky district like South Staffordshire. This objection, however, could only apply to their use for buildings of architectural pretensions, and such buildings in the black country do not predominate. There is every reason to believe that this method of utilizing the innumerable dusky hillocks which disfigure the South Staffordshire landscape will gradually develope into an industry of some importance. The material is to be had in any quantity for a mere nominal sum, and its exhaustion in those parts of the district where the collieries are worked out would be doubtless followed by a restoration of the landscape to a much nearer resemblance than it now bears to its former beauty.—*The Times.*

The Pharmaceutical Journal.

SATURDAY, JUNE 22, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

REPORTERS AT THE COUNCIL TABLE.

MOST of our readers were probably somewhat astonished at the very full report which appeared in the Journal of the 8th instant of the proceedings of the June Meeting of the Council. The subject which excited most interest and discussion was one that afforded ample scope for the arguments of those who advocate the view that these proceedings are *public*, as well as of those who, on the other hand, maintain their *private* character. Ultimately it was resolved,—"That it is desirable that such reporter or reporters as the Council may desire to invite be allowed the opportunity of reporting the proceedings;" and a Committee was at once appointed to inquire into and report as to the best means of carrying into practice the foregoing resolution.

For the benefit of those who have not closely followed the doings at the Council table, it will not be out of place to mention that a reporter engaged by the Council has been taking shorthand notes for the last year; and that a Committee, consisting of the PRESIDENT, VICE-PRESIDENT, and Mr. SANDFORD, has each year been specially appointed to decide what portion should be published and what suppressed. Accordingly, monthly reports, based on the notes of the shorthand writer, have been regularly furnished to this Journal by the Committee.

It would seem, however, that this system is not satisfactory to the present Council, who imagine that a complete *verbatim* report should, as a rule, be published; and some even affirm the necessity of inviting other reporters, to be paid by the proprietors of any journal that may find it to its advantage to head its report with the magic words, "By our *own reporter.*"

The discussion turned more upon the question as to how much was fit, or ought, in the interests of the Society, to be published than upon the main point of *open* reporting; and the majority of the supporters of the resolution avowed, so far as we can judge from their remarks, the expediency of some sort of control over the publication other than that exercised by the editorial staff of most journals. They did not, and possibly could not, state the nature of the supervision they would wish to see exercised, and left what was somewhat facetiously called this matter of *detail*—practically, the whole subject—to be settled by the Committee first referred to.

It is perhaps needless to say that this question of reporting has been very fully discussed more than once at the Council table, and the conclusion come to that open reporting would not conduce to the material interest of the Society, but might minister to the vanity of tall talkers, and seal the lips of some of the quiet, wise men on whose judgment the Council has often had good reason to rely.

We confess that we regard this view as somewhat overstrained; and indications are not wanting that the old as well as the new element on the Council are at one in their desire to kindle and maintain amongst the members generally an interest in their proceedings. The members themselves have also, in very plain language, expressed their wish to know more about the public business of the Council; but the distinction between public and private business is the difficulty which has to be satisfactorily solved before *open* reporting can be considered to be agreeable to many even of the councillors who spoke in favour of the resolution.

One of our correspondents in last week's issue remarks very justly that it is not only quite usual but the rule for representative bodies, charged with administrative and executive duties, to conduct their deliberations privately, but that legislative functions are properly exercised in public. A glance at the work of the last four years shows that the truly legislative functions vested in the Council are exceedingly few as compared with the executive duties of carrying on what may be termed the trade (is not a handsome profit realized out of it?) of a great examining and educating body having much subsidiary business attached to it. Though we ourselves concur in the opinion that a full report of *most* matters pertaining to the administration of the Society might be published with positive advantage to the Council and gratification to the members, we are bound to admit that it would be impolitic not to have some means by which any one councillor can exercise that absolute freedom of speech which is obviously of grave importance under certain circumstances. Cases of this kind would not be of frequent occurrence but when they have to be dealt with they would be best suited for discussion before the whole Council rather than in any Committee.

We cannot fail to see that, whatever scheme is adopted, the PRESIDENT and VICE-PRESIDENT will have to exercise considerable firmness and judgment to prevent discussions which may tend to lessen the respect we all feel for the Council.

There is every reason to believe that the Committee will solve the difficulty in a manner creditable to themselves and satisfactory to the members.

PHARMACY IN THE SOUTHERN STATES OF AMERICA.

We are frequently applied to for information respecting the rate of payment and the comparative advantages offered to pharmacists in different parts of the world. We are, therefore, glad to be able to give a quotation from a letter upon this subject received from a correspondent at Memphis, Tennessee, U.S. He says:—

"Salaries are much higher here than in England, or even Canada. I receive now 100 dollars, or £20 a month, and shall, at the end of the present month, be receiving 125 dollars a month. Expenses are, however, much heavier, as it is impossible to live here under 600 dollars a year, which, however, leaves a fair margin for saving. Rents are enormous. For the shop and five rooms upstairs, this firm pays £700, or 3500 dollars a year. . . . Good dispensers are well paid here, receiving from 1000 dollars to 1500 dollars a year; but it is difficult for a stranger to get into a place. English diplomas,—of the Pharmaceutical Society, for example,—are highly esteemed, being considered much more reliable than those granted in this country. In fact, of American diplomas those of Philadelphia are the only ones of any value in the south."

We learn from Ceylon that, in consequence of the higher price realized in the home market for the bark of *Cinchona officinalis* over that of *C. succirubra*, considerably more attention is now being given to the cultivation of the former species. A single firm in the island, whose exportation of *C. officinalis* realized in England as much as 3*s.* 3*d.* per pound for unassorted bark, has applied to the Government plantations for as many as 350,000 plants.

In the neighbourhood of Port Lincoln, South Australia, large quantities of the malvaceous plant *Plagianthus spicatus*, Bth., have recently made their appearance, and have proved fatal to cattle and sheep, who appear to be very fond of the young flower-spikes. The plants are stated to appear periodically. One resident communicates to Dr. Schomburgk that he had not seen it in his neighbourhood for fully five years, and never in such large quantity. After a bush fire which happened recently in the district, the plants suddenly sprang up over hundreds of acres of land, and in many places they were so thick that a man could only with difficulty walk through them. They grow to a height of from three to five feet. The tops of the flower-spikes appear to be the parts most relished by cattle and sheep, and these portions are said to be the most poisonous. The first effects upon the animals, after eating them, are described as a kind of trembling, succeeded by a rapid and total loss of muscular power, so that they fall and die in great agony in the course of a few hours. A *post-mortem* examination shows the liver, stomach and viscera to be much inflamed. Hundreds of cattle and sheep are reported to have died from eating the plants. The fact of this poisoning is worthy of note, belonging as the plant does to an order celebrated for its harmless and mucilaginous properties.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

June 14th, 1872.

Present—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport, Gale, Haselden, Ince and Linford.

Forty-five candidates presented themselves for the Modified Examination; of these, *eighteen* failed. The following *twenty-seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bannister, Theophilus Mayo	Nottingham.
Binge, Alfred	Islington.
Biss, John William	Southsea.
Boden, Henry	Tottenham.
Chant, Herbert Alfred	Langport.
Cutforth, John Dixon	Manchester.
Davies, Thomas Burton	Hawarden.
Friend, William	Braunton.
Gorton, Charles	Whitechapel.
Hepburn, John	Fraserburgh.
Hilton, William	Whitefield.
Insull, Edward Samuel	Shelton.
Kitchen, George Seaton	Stamford.
Knight, George Edward Moses	Southampton.
Learoyd, William Valentine	Manchester.
Miller, Henry	Jersey.
Monkhouse, Henry	Derby.
Pechey, Henry	London.
Plumridge, Charles	London.
Pride, Arthur Edwin	Nottingham.
Prytherch, Rees	Llandovery.
Roberts, David Watkin	Chester.
South, George	Camden Town.
Speight, Robert	Lincoln.
Thomas, William	St. Leonards.
Trim, Edmund	London.
Wilcox, William	Dover.

Provincial Transactions.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The monthly meeting of this Association was held on June 7th; Mr. Masters, President, in the chair. There was a large attendance of members. A specimen of *Conium maculatum*, eight feet high, gathered on the previous botanical ramble, was exhibited.

The Secretary (Mr. Druce) read the minutes of last meeting and various letters which had been received during the month, and announced that they had received for their Prescription-Book fifty local prescriptions from Messrs. Tigar and Bird, six of Dr. Ware's from Joseph Ince, Esq., and sixteen from J. Baynes, Esq., Hull, containing specimens of Dr. Humphrey Sandwith's and Sir Henry Cooper's prescribing. Messrs. Evans, Lescher and Evans had kindly promised them a Materia Medica Cabinet, which would be lent to the members for a specified time.

Mr. Lance read a paper on "Myrrh; illustrative of its origin, history, description and preparations."

Mr. Masters read a paper on the "Storage of Poisons," containing many useful suggestions.

Mr. Sheppard read an essay on "Education," which led to a long discussion.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

April 24, 1872.

NUTS, THEIR PRODUCE AND USES.

BY P. L. SIMMONDS.

(*Concluded from page* 1020.)

TURNERY NUTS AND ORNAMENTAL SEEDS.

Of nuts for turnery and ornament there are not many received in this country, but a few have some degree of commercial importance, and one or two others may be incidentally noticed.

Our continental neighbours seem to be more shrewd and clever than we are in applying nuts and seeds to purposes of personal decoration; and although, from being cheap, many of these ornaments are despised by our belles, yet none can deny their interest and beauty and the ingenuity and taste with which they are arranged. The field is an exhaustless one, and many well-known ornamental nuts and seeds of India and South America have not yet made their appearance in this country.

The vegetable ivory nuts of commerce, corosso-nuts as they are usually termed, and tagua by the Indians of Magdalena, are the fruit of the *Phytelephas macrocarpa* a South American palm. The fruit, a collection of from six to seven drupes, forms clusters which are as large as a man's head, and stands at first erect, but when approaching maturity, its weight increasing, and the leaf-stalks, which up to that period supported the bulky mass, having rotted away, it hangs down, and the creeping caudex is seldom higher than six feet. A plant bears at one time from six to eight of these heads, each weighing, when ripe, about twenty-four pounds. The drupes are covered outside with hard woody protuberances. Each contains from six to nine seeds, but generally seven. From the kernels (the hardened albumen) the European turners fashion the knobs of walking-sticks, the reels of spindles, small boxes, and various little toys. It is of the same nature as the nutmeg and the pulp of the cocoanut, which in some palms becomes more hardened. That of the date, the *Raphia vinifera*, the talipat palm, and others, is quite as hard, but it is neither large enough nor white enough to be of use to the turner. In contact with sulphuric acid, the vegetable ivory takes a splendid red colour, almost equal to magenta. This colour, at first pink, then bright red, becomes much deeper and more purple when the acid has been allowed to act for about twelve hours.

The demand for vegetable ivory nuts is largely on the increase for button-making and other purposes; as much as a ton a day is frequently worked up in Birmingham. In 1870 we received 31,430 cwt., valued at about £20,000.

The waste and shavings of this nut furnish a good charcoal, which is utilized by some chemists. A paragraph has lately been going the round of the papers, stating that the turnings and raspings of the nut are used to adulterate ground bones; but this I much question, as they could scarcely be obtained in quantity. The value of the other nuts imported for turning, etc., besides the vegetable ivory nuts, is about £20,000.

The coquilla-nut, the produce of *Attalea funifera*, one of the palms which yield the piassaba fibre of commerce, is another ornamental turning-nut, but of a dark mahogany colour. The supplies of this, however, from South America have been failing, owing to the indiscriminate destruction of the trees, and the nuts imported lately have been small and immature, and therefore not appreciated and useful. The cohune-nut, from another species of the same palm, can also be turned into little articles. In Bogota they have small nuts, exceedingly hard, called toparos, which are often made into tinder-boxes, adorned with silver.

The seeds of the shreetaly, or talipat-palm (*Corypha umbraculifera*), being a species of vegetable ivory, are turned into marbles, beads used by certain sects of Hindoos, button-moulds, and various minute articles. Little bowls and other fancy ornaments are made from them, and when polished and coloured they are easily passed off for genuine coral. These nuts could be obtained in large quantities in Canara, Malabar, and other parts of India; the chief objection is that they are of such small size.

The fruit of the doom-palm is turned into beads for rosaries, and in Africa is made into little oval-shaped cases for holding snuff.

The betel-nut, the produce of the *Areca catechu* palm, may here be incidentally known, because it has been turned into ornamental articles, although its principal uses are for other purposes. Small quantities are imported for making tooth-powder and paste, and as a dog medicine; but in India a large commerce is carried on in this nut, chiefly as a masticatory; catechu is also made from it. Betel-nuts are pale when mature, but dark coloured when collected and dried in an immature state, hence the distinction of red and white nuts in the Eastern bazaars, the former being only half the value of the latter. About 4000 tons of these nuts are annually shipped from Ceylon to different quarters. At Travancore the quantity grown is enormous: in Penang 3000 tons are produced, and in Sumatra 4000 to 5000 tons.

The nuts of various other palms have some few useful applications. The grugru-nuts, the seed of *Acrocomia sclerocarpa*, are turned and carved into very pretty beads, rings, and other small articles, the hard black texture of the nut taking a fine polish.

The albuminous fruit of *Raphia vinifera* are carved into little figures by the African negroes.

Peach, cherry, and other fruit stones are often seen carved and highly ornamented, and made into rosaries, bracelets, etc., evidencing the patience and skill of the workman who has laboured on them. The hard stones of the date-plum and other indigenous fruits are frequently beautifully and elaborately carved by the Chinese and Japanese.

Under the name of Quandung-nuts, the corrugated seeds of the Australian native peach (*Santalum acuminatum*) are often set and mounted for scarf-pins, bracelets, and other ornaments.

The spherical corrugated seeds of *Elæocarpus ganitrus*, and other species cleared of their soft pulp, are used by the Brahmin priests as beads. They are also made into necklaces and bracelets for ladies, which are much admired, especially if gilded or capped with silver mountings. Those of *Monocera tuberculata* are used for a like purpose in Travancore. The nuts of *Putrangiva Roxburghii* (the wild olive), called in Hindostan "Jeeopatra," are strung by the natives, and put round the necks of their children as an amulet.

The seeds of the bladder-nut (*Staphylea pinnata*) are as hard as bone. The nuts, in some parts of Europe, are threaded for paternosters, and made into necklaces and chaplets. They are also called cut-noses and false pistachios. The kernel has a little of the flavour of the pistachio, but is very acrid, and occasions nausea if eaten to any extent. It yields by expression a bland oil.

MISCELLANEOUS NUTS.

Under this last group I may include those used for tanning and other purposes. Among the tanning and dyeing nuts or seeds are valonia, under which name the large acorn cups of *Quercus ægilops* are imported from Turkey. The incipient acorns are called camata and camatina. In 1859, 25,579 tons, valued at £332 527, were imported; last year 27,706 tons, valued at £441,998, were received. Under the name of myrobalans, the dried fruit of some species of *Terminalia*, chiefly *T.*

chebula, are imported, sometimes to the extent of 6000 tons in the year. In 1870, 3000 tons, valued at £33,000, were imported. One species sometimes comes in under the name of Bedda-nuts. From its astringent properties, the dried fruit is much used by the Hindoos in their arts and manufactures. The outer coat of the fruit, mixed with sulphate of iron, makes a very durable ink; hence they are called in the bazaars of India ink-nuts.

The Belleric myrobalan (*T. Bellerica*, Roxb.) is also astringent, and sometimes used in medicine in the East. The kernel of the nut mixed with honey is given in certain cases of ophthalmia. It is said to intoxicate if eaten in great quantity. An oil expressed from the seed is used in India for strengthening the hair. The kernel of the nuts of another species (*T. Catappa*, L.) has the flavour of an almond, and may be used for the same purposes. The oil is very like the almond oil of Europe, both in taste and smell, but becomes turbid by keeping. It only requires care and attention in its preparation to render it of commercial value and importance. To extract the oil, the fruit is gathered and allowed to dry in the sun for a few days, when the kernels are cleaned and bruised in a mill.

Nutgalls, the spherical concretions and excrescences formed upon the leaves and leaf-stalks of several species of oak and other trees in the south of Europe, are made by the puncture of the female gallfly. There are blue, black, green, and white galls; the last are of little value. Those from Aleppo and Mosul are the best; they are about the size of a nutmeg, and mostly of a bluish or greyish colour, hard, heavy, compact, with numerous small tubercles on their surface. The imports in 1870 were 17,748 cwt., of the value of £54,169.

Grey Bondue nuts, sometimes called Nata in India, and in Barbados the horse-nicker or chick-stone, are the stony seeds of *Guilandina Bonducella*. They are intensely bitter, and have hence some medicinal reputation. They are used for playing a game in Western Africa. Ornaments made of them are very common in museums, and I have seen baskets, bracelets, rosaries, and other articles made with them.

The kola-nut of Western and Central Africa, the seed of *Sterculia acuminata*, have attracted some attention from their use in food and medicine by the natives; and after careful analysis, Dr. Attfield found they contained 2 per cent. of theine, which is more than the average in tea and coffee.

The poison-nut, or ratsbane, the seed of *Strychnos Nux-vomica*, is contained in a pulpy fruit, about the size of an orange. As a medicinal agent these seeds possess valuable qualities, but are highly poisonous, except in very minute doses. What is done with the 5000 or 6000 cwt. imported it is difficult to say.

The seed of another species (*S. potatorum*), the clearing-nut, has more useful properties, for they are employed in India to clear muddy water. One of the seeds is well rubbed round the inside of the earthen vessel containing the water, which is then left to settle; in a short time the impurities fall to the bottom, leaving the water clear and perfectly wholesome.

The marking-nut, the fruit of *Semecarpus Anacardium*, is in general use in India for marking cloths with the juice of the pulp; the colour is improved and preserved from running by the mixture of a little quicklime and water.

Under the name of soap-nuts, the round black seed of *Sapindus Saponaria*, *S. emarginatus*, and some other species are much used for rosaries, necklaces, bracelets, and other ornaments. They derive their name of soap berries from the acrid saponaceous pulp being used for washing linen. The kernels of *S. esculentus* are eaten in the West Indies, and deemed as palatable as the hazel-nut or almond.

Horse-chestnuts are much used on the Continent for making starch, and an oil is said to be obtained from them which is sold by some chemists as a sedative in gout.

The drupe of the wild almond of the Cape (*Brabijium stellatifolium*, R. Br.), after having been soaked for some days in water, is eaten by the natives, being considered injurious when quite fresh. The kernel roasted is used as coffee.

Ravensara-nuts are the aromatic fruit of *Agathophyllum aromaticum*, used sometimes instead of nutmegs.

Sassafras nuts, another aromatic seed, are the isolated lobes of the seeds of *Nectandra Puchury*.

Cumaru nuts of Brazil and Guiana are the seeds of *Dipterix odorata*, the tonquin bean of commerce, which yields a pleasant perfume for snuff, clothes, etc. A clear yellow fixed oil is obtained from them, which is used in perfumery and for ulceration of the throat.

I have thus taken a hasty survey of nuts and their products, necessarily, from the wide field I have had to cover, very superficial; but I think those who have followed me in my investigation will admit that it is an interesting subject of inquiry, and that the commercial uses of nuts and their products are of high importance in this and other countries.

PHILADELPHIA COLLEGE OF PHARMACY.

A pharmaceutical meeting was held on May 20th; the President in the chair. On this occasion a presentation was made by the chairman, on behalf of some members, to Mr. Samuel F. Troth, it being the fiftieth anniversary of his election to membership. The gift consisted of a copy of the last edition of the United States' Dispensatory and of Dr. Thomas's Biographical Dictionary, together with a suitable inscription.

Mr. Bullock exhibited the result of drying a film of gelatine on a sheet of glass; in contracting, it was found to raise a film of the glass with it. Mr. Procter had noticed this in a test-tube with glue, though not on so extended a scale.

Prof. Maisch presented to the college a number of specimens of cundurango, sent through Dr. Ruschenberger, U.S.N., by Dr. J. M. Foltz, Surgeon-General U.S. Navy, for the college cabinet. They were collected in the province of Loja, Ecuador, by Passed Assistant-Surgeon Joseph G. Ayres, of the Navy, by official direction, and forwarded with a report to the bureau of medicine and surgery in the Navy Department; a description of the several specimens has been prepared and will probably be published. The specimens comprise pieces of stems, fruit, etc., of the following seven varieties:—Cundurango de tumbo grande, de tumbo chico (Bejuco Pachón), de Paloma, de Platano, de cascarilla, Saragosa and blanco. Prof. Procter raised the question whether cundurango was the same as guaco, which has been sold in European markets as cundurango, and whether any authentic case of cure from the use of this remedy is known. Prof. Maisch stated that he had never seen guaco sold as cundurango in our market, nor had he read of the cure of a case of cancer in any of the medical or pharmaceutical journals, and stated that none of the physicians whose names were mentioned in connection with its successful use when first introduced now claimed anything for it; some publicly declare they had nothing to do with the publication of their names as recommending it.

Mr. Remington spoke of an adulteration of iodine which recently came under his notice. Upon examination this sample was found to contain about 25 per cent. of sawdust. Mr. R. stated that the adulteration was very easily detected by close examination, or by one accustomed to handling the article. It was suggested by members that the sawdust may have become mixed with the iodine through breakage, the iodine having been packed in it for transportation. The adulterant seems almost the last that would suggest itself, on account of its lightness. The result of further investigation will be interesting to the profession at large.

Prof. Maisch exhibited a fine sample of round cardamom (*Amomum Cardamomum*), very rare in the Philadelphia market.

The Professor also exhibited crabs' eyes, which were enclosed in a small bag in an original package of cantharides. The question arose as to the cause of this; and as crabs' eyes are thought to be about as expensive as cantharides, it is doubtful whether this can be called an intentional fraud.

A curious specimen of colchicum was also shown, cut in transverse slices, externally white, internally quite dark in colour.

The Professor also exhibited to the College a fine sample of Chinese blistering fly (*Mylabris Cichorii*), said to contain one-third more cantharidin than Spanish fly of European commerce. These flies differ from the *Cantharis vesicatoria* in some particulars, and are devoid of the peculiar green lustre on the wings. Some discussion ensued as to the principle, cantharidin, and its development in the fly, as being connected with the genital organs of the female fly, and being present only at a certain stage in its life. The Chinese fly is imported into the London market at about half the price of the officinal fly.

Prof. Procter spoke of *Cantharis atrata*, which is not a Mylabris, and which he has had for some time.

This was the last meeting until the autumn.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Monday, June 17th, 1872.

Metric System of Weights and Measures.

Mr. J. B. Smith asked the President of the Board of Trade whether he intended to bring forward any measure to relieve persons who, acting under an Act of Parliament passed in 1864, which declared "it is expedient to legalize the use of the metric system of weights and measures," make use of the same, but who, according to the opinion of the law officers of the Crown, were liable to be prosecuted if such weights and measures were found in their possession; and whether he intended during the present session to bring in a general measure for the regulation of weights and measures.

Mr. Fortescue said the question was, to a certain extent, founded upon a misconception of the Act to which it made reference, for, while the preamble of the Act declared that it was expedient to legalize the use of the metric system of weights and measures, the enacting part only legalized contracts made under that system. The Standards Commission had, however, recommended the permissive legalization of the metric system; and he might say that any bill he might bring in would carry that suggestion into effect. He did not see any prospect of introducing the bill during the present year.

PAPERS PRESENTED TO PARLIAMENT.

Report on Certain Sizing Processes used in the Cotton Manufacture at Todmorden, and on their Influence upon Health.

In July, 1871, a memorial was presented to the Lords of Her Majesty's Council, signed by 1650 weavers of the Todmorden district, representing that the use of kaolin or China clay in the cotton manufacture has during recent years been largely adopted, and led to the use of large quantities of sizing to cause it to adhere to the warps. The petitioners believing that the practice was very injurious in consequence of the poisonous nature of the ingredients used,* and the want of ventilation in the weaving sheds, prayed that a medical inspector might be sent to inquire into the system generally. Dr. Buchanan was, therefore, instructed to visit the district and investigate this subject, and from his report, which has just been laid before Parliament, we extract the following. Premising that although his personal investigation had been confined to the district of Todmorden, he had been informed that processes similar to those there observed, more or less modified, were widely employed in cotton factories throughout Lancashire and Yorkshire, he proceeds to give some history of the origin of the practice.

"Up to twenty years ago, 'sizing' of cotton consisted in the use of some fermented flour and tallow, in order to give tenacity to the warp and to lessen friction in the weaving process. The amount of such size required for this purpose to cotton of the quality that was usual twenty years ago, averaged for ordinary cotton goods about 20 per cent of the weight of the warps. About twenty years ago, it was observed by some sizers that the brownish colour given to cotton cloths by size made from inferior kinds of flour could be reduced by the addition of a small quantity of China clay to the size; and further, that this material so far reduced the glutinous quality of the flour that the sized warps would weave easily with a less amount of tallow in the size. In 1854, at the time of the Russian War, the increased price of the usual sizing materials led to further substitution of China clay. Some manufacturers, when these facts came to their notice, would have nothing to do with the new substance, and insisted on having the desired whiteness and freedom in weaving by the use of good flour and tallow in the size. But other firms were content if they got the results they wanted in the appearance of their cloth, and could get their sizing done more cheaply by employing sizers who used China clay. This was the first stage in the use of the substance, a certain quantity of the clay entering into the composition of the size, and the number of factories becoming more numerous that used such sizing; but the total amount of size in proportion to cotton not becoming materially increased.

"This was the state of matters, when, in 1862, the American War produced the English cotton famine. Cotton then very rapidly rose in price, and the better sorts were almost unattainable. Now it appears that warps of shorter fibred cotton are difficult to weave, unless the needful tenacity of the twist be given by a larger amount of size than would be wanted for better sorts. Of size, made of flour and tallow, warps from the worse kinds of cotton are stated to require even more than 20 per cent of their weight. The product is, of course, worse in quality than cloth made from better raw material; but as poor cotton had to be employed, it was necessary to use such quantity of size as would allow it to be woven.

"But the lack of cotton in 1862 introduced another practice. Weight for length had been, as it still is, the chief test of the goodness of any description of yard-wide cloth; and with the scarcity of raw material came the practice of giving a fictitious weight to cloths containing less cotton, in order to make it appear that they contained more. It became a matter of rivalry with sizers, which of them could, on the order of manufacturers anxious to meet the demands of merchants, 'put on' most foreign matter upon the cotton warps.

"From this practice of 'heavy sizing' the more reputable manufacturers long kept aloof, but they did so at the expense of their immediate trade; and for the last three years every yard of cotton cloth made at Todmorden, and many other places, has been weighted with quantities of size, not required for any manufacturing purpose, but used as an adulteration."

Dr. Buchanan then gives some information as to the nature of the size used:—

"The 'size' that is thus put on to cotton warps is of various composition. It may still consist, in the main,

* See a case of poisoning by a baryta sizing compound reported last week, p. 1021.

of flour and tallow, some sort of salt being added either for the purpose of lessening the glutinous quality of the flour (which otherwise would, when used in quantity, stick the warps together) or else for the further purpose of retaining moisture, and thus of increasing weight. Epsom salts and chloride of magnesium (with sulphate and chloride of zinc, not yet in common use at Todmorden) have been the principal salts used for one or both of these purposes; and these substances go by the generic name of 'antiseptics,' a name which would appear to belong more properly to those of the salts which have the further property of preventing mildew in the artificially weighted cloths. This class of substances is that to which the memorialists refer as 'poisonous ingredients.'

"The salts above mentioned are not in the ordinary sense 'poisonous;' that is the small quantity of them that comes off the cotton warps in the weaving process would not, if taken into the stomach, kill a person. It is indeed asserted that more mischievous substances have for their 'antiseptic' properties been put into size. These are the terms in which a newspaper refers to certain of such: 'Size is fermented vegetable and animal matter; and when once life, vegetable or animal, has been started in it, it is rarely and with great difficulty extinguished.' And here again comes another source of mischief. The antiseptic Mr. Molesworth so mysteriously vapours about, is an addition intended, practically speaking, to keep the mixture of cotton size and clay from vegetation, and as a rule, consists of alum, arsenic, or baryta. None of these compounds are desirable elements of our daily bread or food, but their effect and quality have also been exaggerated.'

"After the best inquiries I was able to make, I have satisfied myself that this statement, so far as regards the use of arsenic and baryta, has no application to the process of sizing as practised at Todmorden. It will subsequently be seen that this opinion is supported by chemical analysis. I think it doubtful whether arsenic has anywhere been at all commonly used.

"But, although the sizing that shall give the desired amount of weight does not necessarily include China clay, yet in practice, that substance is far most commonly added in heavy sizing; for not only does it give a whiteness to the over-sized cloth, and help the weaver by 'opening the twist' (that is, lessening the cohesiveness of the warp threads that would result from the over-use of the flour-size alone), but the clay itself serves, with particular efficiency, the desired object of giving weight to the cloth. One-third of clay (33 to 37 per cent.) is the usual proportion for these purposes introduced into 'size,' the remainder of the size consisting of flour and some fatty substance, with or without one or other of the so-called 'antiseptics,' and perhaps, also, some animal glue or rosin. The composition of the size, and the proportions of its ingredients, vary in different factories and with different sizers, and the minuter processes upon which depends the ability to get the greatest amount of size upon the warps, are frequently trade secrets with particular sizers. In general terms, however, the practice of sizing at Todmorden, for the kind of cloths that are made there, consist in putting on to the warps from 50 to 90 per cent. of 'size,' one-third of which consists of China clay. The chief differences consist in the amount and nature of the fatty substances used, and in the employment or not of some or other 'antiseptic.'

"The adherence of China clay to the warp is much affected by these differences. Whatever the other ingredients of the size, some of the clay comes off in the weaving process. That quantity is smaller when the rest of the size consists of flour and fatty matters only; larger when the fatty matters are in smaller quantity, and when 'antiseptic' is used."

One subject alluded to in the memorial was the imperfect ventilation and humidity of the weaving sheds. In weaving warps of inferior cotton, weighted with China clay and flour mixed with deliquescent salts, there is especial occasion to keep the weaving sheds damp, as in this way the brittle compound of cotton, flour and clay is less liable to break, the clay comes off less, and the resulting cloth is also heavier by the weight of the retained moisture. The conditions most favourable for retaining in the air the moisture desired for facility of weaving, were at the time of the inspector's visit secured by windows and so-called "ventilators" being habitually kept closed.

With regard to another point, the diffusion of dust in the air, Dr. Buchanan reports that he visited seventeen weaving sheds on the premises of twelve manufacturers. In four sheds, belonging to two manufacturers, there was, in daylight, no perceptible haze in the atmosphere. In all the others there was more or less of haze, caused by very fine particles of dust. In all the sheds there was more or less dust on every surface where it could settle, and this though the floors and looms had been cleaned of the dust on the previous evening, or in the course of the same day. This dust was generally loose, but in one or two establishments it tended to adhere to the floor. These were places were sizing was done in the establishment, and where fatty material, but no 'antiseptic' was used. The looms were, in all cases, covered with opaque dust, varying in amount from a slight bloom, in the sheds of the just-mentioned establishments, to a thick layer in some other sheds. The quantity of dust was found to depend, in part, upon the sort of cloth that was being made. In the most dusty sheds the clothes and hair of the weavers were seen covered with fine white dust. Further, the stranger-visitor experienced, in all the more dusty sheds, and roughly in proportion to the amount of visible dust, very great irritation in the nose, and in a less degree to the eyes and throat. To this irritating effect of the dust, a frequent visitor, and still more a weaver, gets speedily accustomed; though there is a certain number, apparently a minority, of weavers who remain incommoded by it whenever their work is more than usually dusty. Of course there is no cause for satisfaction in the deadening of sensations that should be sentinels against irritating matter entering the throat and lungs.

Respecting the matters composing this dust, analyses, made for the purposes of this report by Dr. Dupré, show that there is a good deal of agreement in its general composition; the chief difference consisting in the proportions of the several substances composing it. None of the more poisonous minerals were found in any of the specimens examined. One-third to one-half consisted of clay in its ordinary sense (*i. e.* anhydrous clay, with the addition of about one-eighth its weight of moisture).

"As for the China clay, against which especially the representations of the Memorialists were directed, the statement is confidently made by manufacturers that, through its weight, the particles must fall directly downwards from the looms, and cannot reach the face-level of the workers who stand over them. This statement is little less than absurd to any one who goes, without preconceived notions, into an average Todmorden weaving shed. Wherever dust can lodge, at all levels of the shed, on the hair and caps of the workers, on the heating-pipes eight feet from the ground, everywhere the dust is of the same opaque, white kind. When the gas is lighted, the spaces between the lights are white in the weaving-sheds, while in the adjacent throstle-room the spaces between the gas jets are perfectly black. That this dust is, in effect, the China clay, quite as much as other matters, has been proved by direct experiment."

It is alleged by some of the manufacturers that men employed at the extremely dusty works in Devonshire and Cornwall, where this clay is obtained, are healthy and long-lived; to which statement Dr. Buchanan thinks it enough to oppose the high mortality from lung-diseases among potters, employed under in-door conditions, much more nearly resembling those of these cotton weavers.

"Examining the yearly death-rates of Todmorden from lung diseases and consumption together, and comparing them with the corresponding rates of England at large, there is found to have been in 1851–60 no excess of such mortality among persons of the middle period of life (the figures are 467 against 448), but some excess among persons over 55 years of age (1340 against 1190.) The Todmorden death-rates of the last few years, as compared with those of ten years ago, from lung disease and consumption, show only one important change, and that consists in a considerable increase (from a rate of 1340 to a rate of 1860) of such mortality among people over 55 years old.

"Examining the mortality registered as from lung diseases separately from that registered as consumption, there would appear to be great and growing excess of 'lung diseases' in Todmorden; while there has been a lower death-rate from 'consumption' there than in England, and this death-rate is less now than formerly. However, experience has shown that in an instance like the present, it is unsafe to draw inferences from the death returns, in regard to the prevalence of the one class of diseases apart from the other, as the appearance of disease in the death register under the one or the other class may be more a question of nomenclature than of facts.

"All the medical men in Todmorden agree that lung diseases are greatly prevalent there, and that the circumstances of employment in the cotton manufacture conduce to such diseases. There is a general agreement too that cotton-workers, with a family tendency to consumption, have that tendency developed; and that those who, without such tendency, continue to work in mills up to 40 or 50 years of age, very commonly break down with lung disease. It is also agreed that they suffer much, and more than other people from dyspepsia. But here the general agreement ends. Respecting the particular occupational circumstances that bring out consumption, or that cause lung disease and dyspepsia, there is difference of medical opinion. While some of the doctors are disposed to ascribe these diseases to sudden changes of atmospheric moisture and temperature, to want of care about clothing, and to hastily swallowed meals, others recognize the dust produced in the cotton mills as being a potent additional cause of each of these maladies. Respecting any change in prevalence of these diseases among weavers, since the practice of heavy sizing was introduced, and respecting the degree of this prevalence among weavers as compared with people employed in other branches of work, there is again difference of statement. On the whole, medical opinion inclines to there being more ill-effect on the lungs of weavers now than formerly, and to the weavers approaching now more than formerly to carders in their liability to chest complaints.

"There can be no doubt that there is a widely spread, though not a universal, belief among weavers in the injurious effects of 'China clay.' I was given the opportunity of personally conversing with twenty weavers, who thought they had been injured by the processes newly incident to the occupation of weaving, or as they put it, by the China clay. They were of various ages, and both sexes, and had had experiences of weaving of very various duration. The commonest complaint among them was shortness of breath coming on at various times after they began weaving, incapacitating them from any active exertion, and ceasing quickly in such as changed their employment for home or out-door work. Among eleven who had experienced this, four, aged respectively 53, 50, 39 and 19, had distinct emphysema of the lungs; one, aged 18, with family history of consumption, had some consolidation of the apex of one lung; and another, aged 19, had a questionable similar consolidation. Three others had suffered, or were suffering from bronchitis. Of the 20 persons, ten gave the history of prolonged subacute dyspepsia. Four had suffered under more or less permanent epistaxis.

"By the persons themselves, often with medical authority, these complaints were connected with the conditions of occupation in the weaving-sheds. Besides that, the ailments had ceased, or had been relieved by cessation of such occupation; statements, apparently trustworthy, were made by several of the weavers, that the more dusty sheds increased the intensity of symptoms, and two of them, who had had long experience of particular establishments, spoke with confidence to having begun to suffer in their chests only after the introduction of new methods of sizing. All the weavers who were questioned stated that they knew of other weavers who had suffered in some similar way to themselves. A very intelligent overlooker, who accompanied me through one of the most important establishments of the town, expressed his own belief that weaving was not so healthy a branch of the cotton manufacture as before heavy sizing was in vogue, and that fewer weavers now pass middle age without getting something the matter with their lungs."

Such then are the facts Dr. Buchanan has been able to gather, bearing on the relation between disease and the heavy sizing processes used in Todmorden. The evidence proves, he thinks, that a slow but certain injury to health results from the circumstances under which weavers work at Todmorden.

Experience tells that the diseases, set up by dusty occupations are not, as a group, rapidly fatal. During the years that their victims are only disabled (and even disablement comes but slowly), no record is kept of their prevalence. When at last they kill, perhaps after having driven the worker to some other occupation and having made his life miserable for ten or twenty years, then for the first time they get registered.

These conclusions are of quite exact application to the sizing processes in use at Todmorden. Of late years by the use of excessive quantities of 'size,' the amount of dust in the process of weaving has been enormously increased, until it has come to pass that in many mills, weaving makes more dust than carding. Accordingly, we have already an increase in the previously high death-rate from lung diseases and consumption together among residents in the town who have passed fifty-five years of age; an increase that, under these circumstances, and in view of the fact that it all appears on the registers as lung disease and not consumption, must be presumed to result essentially from an increase in those prolonged and miserable diseases that are engendered by dusty occupations. Unless, therefore, in the practice of sizing, or in other ways, important changes occur, it is to be expected that the already excessive and increased mortality will still further increase; for the dust diseases are slow in their nature, and the heavy-sizing processes that are giving rise to them have not yet had time to produce their full effect.

Action for Libel brought by a Pharmaceutical Chemist against a Surgeon.

Court of Exchequer, June 17th. (Sittings at Nisi Prius, at Westminster, before Baron Martin *and a Special Jury.)*

Booth *v.* Forsyth.

Mr. Huddleston, Q.C., and Mr. J. O. Griffits were counsel for the plaintiff; and Mr. Digby Seymour, Q.C., and Mr. Benjamin appeared for the defendant.

This was an action of slander brought by a pharmaceutical chemist at East Greenwich against a surgeon. The slander complained of, the plaintiff alleged, wa uttered in the presence of a Doctor Saundry, as they were leaving the residence of a Mr. Downs,, on the Marshes. The defendant said to the plaintiff, "I have an important case down in the Marshes where you have been supplying medicine to procure abortion. To be plain with you, the eyes of the police are upon you. I have some of the medicine, which contains a sediment, and I intend putting it under a microscope. There has been a good deal of amateur doctoring going on in East Greenwich lately. This is a serious case, and I cannot screen you." To this plaintiff said he replied, "Really, Dr. Forsyth, you must be in error. All that I know is, a female called at my shop on Tuesday, suffering from diarrhœa through taking aloes ('pilacotia'), and I gave her a bottle of mixture, and she went away. She subsequently called with her mother, a Mrs. Green, and stated that the relaxation had ceased, but she was suffering from pains in her loins and bearing down, and after referring to Dr. Lee's book on the practice of midwifery, and suspecting from the symptoms what was the matter, I prescribed for her from that work, and charged her 1*s.* 3*d.* for it, and told her, with rest, she would be better." It appeared that afterwards, meeting Dr. Forsyth in the street, the plaintiff asked him if he intended apologizing for the charge he had made against him, to which the defendant replied, "No, not I. I've got you now, and before I've done with you I'll see you leave Greenwich; you know you are not a qualified man to supply medicines, and I'll make you smart for it."

In cross-examination the plaintiff denied that the words were, "I've just come from a woman who says you have given her something to procure abortion." He admitted that he had given a Mrs. Sargeant a lotion for her legs, and that it contained prussic acid, and she had taken it instead of her medicine; and several doctors, including the defendant, were afterwards in attendance upon her. He had given a woman solution of strychnine to kill bugs, and it required water to be mixed with it before using it, but he could not undertake to say he had given written instructions as to how much water was to be mixed with it. He was sure he had told her verbally how to mix it. Upon being asked why he sold such things, he said he did so in self-defence, as other chemists did it. Upon being asked by Mr. Digby Seymour what "pilacotia" pills were, he replied, the refuse aloes of a chemist's shop which could not be used in finer pharmacy. He denied that he was aware that "pilacotia" was used by the lower order of persons to procure abortion, but he knew that if given to a woman far adadvanced in pregnancy, such pills had a tendency to bring on premature labour.

Dr. Saundry was called to corroborate the plaintiff as to the words of the slander; and a police-inspector was called to prove that the defendant was surgeon to the police force, and that he had spoken to the defendant, who, upon his advice, had gone to the police magistrate.

The defendant denied that he had made use of the words imputed to him, but stated he met the plaintiff and Dr. Saundry as they had mentioned, and upbraided the plaintiff, saying that he had been called to see a woman who was very ill, and she had told him that she having had two children, and being again in the family-way was desirous of procuring abortion, and went with two other women to buy some "pilacotia." One of them bought a pennyworth, which was divided among the three. The object not being accomplished, she purchased a pennyworth for herself, and took it, and this produced diarrhœa. She then called on the plaintiff, and told him what she had done, and he gave her a draught to stop the diarrhœa. She got better and called on the plaintiff again, and then he gave her a bottle of medicine, which she said she had taken doses of. He then looked at the bottle, and it appeared to contain a solution of aloes. He examined the woman, and believed that her state was brought on by the taking of these aloes for the purpose of procuring abortion. After this statement had been made to the defendant, he went to see Mr. Downs, and, seeing the plaintiff there, followed him afterwards and made the statement mentioned above, fully believing that the woman's statement was true. An analytical chemist was called to prove that the bottle produced contained nothing but aloes; and in an advanced stage of pregnancy, such a mixture was like to bring about premature labour.

The plaintiff was recalled, and swore that the contents of the bottle produced were never sold by him either to the woman or anybody else.

After Mr. Digby Seymour had summed up his evidence, and Mr. J. O. Griffits had replied on the whole case,

His Lordship left it to the jury to say whether, if they believed the plaintiff and Dr. Saundry, there could be any doubt that the defendant charged the plaintiff with having sold medicine to procure abortion, and, as such a thing was a crime in this country, it would be slanderous to say so; or whether they believed the defendant's statement as to what he said, and, if so, his Lordship thought it would not amount to a slander. If they found for the plaintiff, then the question would arise as to the amount of damages; and upon that they must be guided by their opinion as to whether the defendant acted fairly upon the information which he relied upon, and if he did, the damages, they might think, ought to be small; or whether the defendant was actuated in what he did, as suggested by Mr. Griffits, by the fact that his practice was more or less prejudiced by the legitimate business of chemists who were nowadays so much resorted to by the poorer classes, and if he was, then the plaintiff would be entitled to substantial damages.

The jury immediately found for the plaintiff—Damages, £50.—*Abstracted from The Times.*

Review.

Lecture Notes for Chemical Students. By E. Frankland, D.C.L., F.R.S. Vol. II. Organic Chemistry. Van Voorst. 1872.

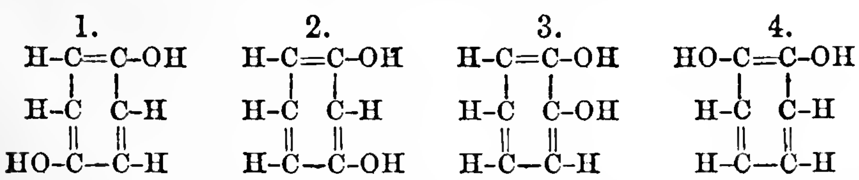
In general arrangement and in detail this new edition of Dr. Frankland's Lecture Notes is very much like the first; but valuable additions have been made relating to compounds of recent discovery, especially in the sections treating of the alcohols and acids. Under the head of Acetylene, however, we miss two reactions of great importance, viz., the conversion of that hydrocarbon into benzol by polymerization, and into hydrocyanic acid by direct combination with nitrogen.

The Aromatic compounds are treated in this edition according to Kekulé's theory; but we cannot say that the account given of them is satisfactory or well brought up to the present state of knowledge. In the first place, with reference to the hydrocarbons, it is stated (p. 42) that "the following six members of this series are known, viz.:

Pentol	C_5H_4	Xylol.	C_8H_{10}
Benzol	C_6H_6	Cumol	C_9H_{12}
Toluol	C_7H_8	Cymol	$C_{10}H_{14}$."

Now, this list is redundant at the beginning and deficient at the end. Cymol is not the highest known term of the series: for hydrocarbons have been prepared containing $C_{11}H_{16}$, $C_{12}H_{18}$ and $C_{13}H_{20}$, the first indeed in three isomeric forms, viz., $C_6H_5.C_5H_{11}$, $C_6H_3.CH_3.(C_2H_5)_2$, and $C_6H_3.(CH_3)_2.C_3H_7$; and with regard to the so-called pentol C_5H_4, we believe we are correct in saying that the most remarkable circumstance connected with it, and with the acid $C_6H_4O_2$ (benzenic acid) from which it was said to be derived, is their non-existence. If, indeed, the existence of a hydrocarbon C_5H_4 were established, and it could be shown, by its properties, to be a true homologue of benzene, then the whole theory of the aromatic bodies at present received would fall to the ground; for it would be impossible to represent such a body by any structural formula analogous to that of benzene. All this was pointed out long ago by Kekulé.*

The important subject of isomerism amongst aromatic bodies is scarcely brought out with sufficient clearness. Particular instances of isomerism are indeed given (though in the case of the hydrocarbons it has been almost overlooked), but there is no distinct indication of the two kinds of isomerism so well displayed in this group of bodies,—the one depending on the circumstance that the replacement of hydrogen by other elements or radicals may take place either in the principal or in the lateral chains; the other, on the relative position of these substituted radicals in the principal chain itself. This is well known to be a real distinction, corresponding to important differences of character in the respective isomerides. In one instance, however, Dr. Frankland has indicated a possible case of isomerism which has been overlooked by Kekulé, and indeed by every one else who has attended to the subject. Oxyphenol $C_6H_6O_2$ or $C_6H_4(OH)_2$ is known to exist in three modifications, viz. resorcin, pyrocatechin, and hydroquinone, the constitution of which is represented by the first three of the following figures, and these are commonly supposed to be the only modifications possible:—



But Dr. Frankland points out that a fourth modification is possible, namely, that represented by the fourth figure, which differs from the third in this respect, that the two groups OH are attached to carbon-atoms which are linked together by two bonds, whereas in the third figure they are attached to carbon-atoms linked by only one bond. This is certainly a difference in the formulæ; but whether corresponding derivatives exist, exhibiting any corresponding differences in their properties, is a question for future investigation. The difference, if any, would probably be but slight; for, after all, each of the carbon-atoms in question is attached, in both cases, to one of its neighbours by two bonds, and to the other by one. The point is, however, of importance: for it clearly affects many other isomeric bodies of the aromatic group besides the oxyphenols; for if this distinction is a real one, there should be four dichloro-, dibromo-, di-iodo-, and di-nitro-benzols; four xylols, four cresols, four toluidines, four acids $C_7H_6O_3$ (salicylic, etc.), four phthalic acids $C_8H_6O_4$, etc.; in short, four di-substitution derivatives in every case. It is remarkable, however, that in all the numerous cases of this kind hitherto investigated, the maximum number of isomerides actually obtained, is not four, but three.

There are one or two peculiarities of nomenclature in Dr. Frankland's work which it may not be superfluous to notice. On pages 66, 67, phenylic alcohol and its homologues are called *tertiary alcohols*, whereas in the first edition of the Lecture Notes, they were called *secondary alcohols*. Now they resemble the secondary rather than the tertiary alcohols in one respect, namely, in having the carbon-atom which is associated with the group OH, directly combined with *two* other carbon-atoms; but altogether their resemblance either to the secondary or to the tertiary alcohols of the fatty series is but slight, and it is better to designate them by a particular term, namely *phenols*, as is now generally done.

On pages 55 and 97, the nitriles are spoken of as *abnormal* cyanides. We submit that they are the *normal* cyanides, represented by the formula $C\left\{\begin{matrix}N'''\\R'\end{matrix}\right.$ and corresponding to the normal cyanic ethers $C\left\{\begin{matrix}N'''\\(OR)'\end{matrix}\right.$, discovered by Cloez, which, when treated with alkalis, are resolved into cyanic acid and the corresponding alcohols.

The graphic or constitutional formulæ in the present edition, are greatly improved in simplicity and clearness by the omission of the circles, which in the first edition were placed round the symbols of the elements; in fact, these circles, which were very much the fashion some years ago, represented nothing at all, and served only to confuse the formulæ.

We should have rejoiced also to bid farewell to the thick black **C**'s and other capitals which disfigure the formulæ without adding anything to their clearness, and to the numerous special symbols, such as Me, Et, Pr, Bu, Ay, Ph, etc., for alcohol-radicals, and Ho, Ko, Zno″, Eto, Aco, etc., for oxygenated radicals. These symbols save but little space, while their excessive multiplication is a tax on the memory, and renders the formulæ difficult to read. The perfection of a symbolic notation consists in the expression of ideas by combinations of the smallest possible number of arbitrary symbols.

Obituary.

ROBERT WIGHT, M.D., F.R.S., F.L.S., etc.

Science has lost one of her best workers, and Indian Botany one of its brightest ornaments, through the death which we record. Dr. Wight died at Grazeley Lodge, Reading, on the 26th of May, aged 76.

Dr. Wight was born at Milton, Duncra Hill, East Lothian, on July 6th, 1796, and took his degree at Edinburgh, in 1816. Soon afterwards he entered the East India Company's service, serving first as Assistant Surgeon, and subsequently as full Surgeon in the 33rd Regiment of Foot. During this time, travelling from place to place, and throughout his long life in India, he devoted extraordinary talent and energy to the collection, description and illustration of Indian plants. In 1834, whilst staying in Edinburgh on furlough, he published, in conjunction with Professor Arnott, of that city, the first and only volume of 'Prodromus Floræ Peninsulæ Orientalis' (1834), a work that has been spoken of as "the most able and valuable contribution to Indian Botany which has ever appeared." Dr. Wight's return to India, however, did not allow of the completion of the work.

The success of this publication had the effect of stimulating Dr. Wight to further exertions, and, on his return to Madras, he commenced a very valuable work, entitled 'Illustrations of Indian Botany,' two volumes of which were published, containing 182 coloured plates of various Indian plants. This work was followed by a still larger one, entitled 'Icones Plantarum Indiæ Orientalis,' which consisted of valuable descriptions, illustrated with 2101 uncoloured plates. After this appeared a third illustrated work on the flora of the Neilgherries, entitled 'Spicilegium Neilgherrense.' The illustrations of all these works are very good; and one cannot but be impressed with the indomitable perseverance shown by Dr. Wight in the success and fidelity of their production at a time when lithography was in a very rude state in India.

Besides these large publications, a great number of memoirs by Dr. Wight are to be found in various botanical journals. Very many valuable medicinal and other useful plants have been figured and described by him. We need only mention as illustrations: *Tylophora asthmatica*, *Argemone mexicana*, *Calysaccion longifolium*, *Mesua ferrea*, *Vateria indica*, *Ailanthus excelsa*, *Rhus succedanea*, *Moringa pterygosperma*, etc.

Dr. Wight paid great attention, not only to the developing of Indian products, but also to the introduction of other articles, such as tea, cinchona and cotton. He was for a long time superintendent of the cotton plantations at Coimbator, and published various memoirs on the subject of cotton. Dr. Wight retired finally from India in 1853, and, since that period, has been working at the Indian Flora as much as his health would allow; and by his notes and materials largely assisting others working in the same field. Dr. Wight was married in 1838, and leaves a widow, four sons and a daughter. In presence of so much work accomplished, as shown in this slight sketch of one of the ablest Indian botanists that ever lived, and remembering the labours of Roxburgh, Griffith, Royle and others, one is tempted to use the phrase, "There were giants in those days."

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Preliminary Examination.

Sir,—If your correspondent, "One who has known the Drug Trade more than Forty Years," has not misunderstood the nature of my argument, he certainly is mistaken as to facts.

The youth in question ought to have been able to pass the Preliminary, but certainly was not. So far, however, from his having gone back and being less fitted for the examination than when he left school, such is very far from the case. I think your correspondent cannot fairly deduce any such inference from a careful perusal of my letter.

In one respect we both agree as to the desirability of taking no youth as apprentice who is not able to pass his Preliminary. But seeing the desirability of a thing, and making oneself a martyr to an idea, are quite two different questions. I for one do hope, however, for "the good time coming," and will do my best to help it on.

As we all ought to have the well-being of the rising generation of chemists and druggists at heart, it might be generally useful if your correspondent would inform us how many apprentices he has had who were able at the end of their time to pass the Minor examination, and the method adopted in their instruction.

One who has known the Drug Trade More than Thirty Years.

The Possibility of Effort.

Sir,—I always read Mr. Ince's communications to the Journal with pleasure, and often with profit, and I can fully appreciate the feeling of weariness with which he took up his pen for the twentieth time, to reply to an inquiring student in last week's Journal, and it may possibly scarcely become me to remind him of the many examples of love, patience, and kindness inculcated in the volume he often so felicitously quotes, and of the necessity, in teaching youth, of giving line upon line and precept upon precept.

The inquiry made of Mr. Ince by the young man is one that a great many others would like to see answered, for most assuredly in many corners of the country, a large number are in a complete fog; and excellent as Mr. Ince's reply is, I fear it conveyed but little comfort to the inquirer.

Now to every young man whose conscience is at all disturbed by the momentous question of, What shall I do to prepare myself for these examinations? I would say, Have you passed the Preliminary examination? or are you prepared to do so? If you are not so prepared, then your duty is plain and direct; and the less you let your attention be occupied by any other subject, the better.

The Preliminary examination embraces three subjects; Latin, English and arithmetic. Now it should be borne in mind that a good knowledge of these is the key that enables a student to unbar the door to all the rest that he has to learn. The more thoroughly he is master of these, the more easily he will grapple with the other subjects.

If the Preliminary has been passed, then those subjects required for the Minor and Major, viz. Chemistry, Botany, and Materia Medica, may be commenced; and an attentive student may make some progress by merely studying the elementary parts of the text-books generally made use of. (I am assuming the absence of a competent teacher.) But what he will be able to study most profitably is the Pharmacopœia and Materia Medica. It is necessary to almost know the Pharmacopœia off by heart. If one who has passed either of the examinations be within reach, he would be able to give good advice "How to do it," much better than pages of written matter.

The mistake too often made by young men is, that because they feel it impossible to grasp the knowledge necessary for the examinations in a short period of perhaps six months, that it is quite useless to make the attempt; but true knowledge is of slower growth than this, and it is only by a long contemplation of any subject that knowledge becomes imbibed. Having by reading and study got some of the leading principles of those sciences and branches of knowledge required for an examination, the student is then in a favourable condition to receive instruction from a teacher or professor, and may then make good progress, and his stay in school or college will be very much shortened, and his task made agreeable, because now he begins to see things clearly, which before he saw but dimly and darkly.

To those who live in small country towns where no lectures can be delivered, and where there is no aid at hand, I would say, do what you can during your apprenticeship by reading those elementary books used as text-books, and which can be purchased for a few shillings. Let your whole aim and object be directed during this period to this one point, of preparing for a systematic study, and submitting to an examination, and let your mind glow with the imagination of the pride and satisfaction you will feel when it is accomplished.

Shade of Paracelsus.

The Preliminary Examination.—*T. B.* has favoured us with a communication relative to the failure of so many young men to pass their examinations. He says that from the town in which he resides, containing 120,000 inhabitants and upwards, of sixty chemists and druggists, employing a large number of apprentices, etc., many have presented themselves for examination during the last twelve months, but only two or three have succeeded. The want of sufficient preparation from which this arises, he attributes partly to the long hours of business, and also to the fact that after a long day's work, employers, otherwise willing, are unfitted and unable to assist their employés in their studies. *T. B.* considers that a remedy might be found in the appropriation of portion of the Pharmaceutical Society's funds to the assistance of pharmaceutical education in the provinces. He suggests that an instructor should be nominated by the Society, in each large town, to whom students might go, upon certain payments, and that an additional sum should be given to such instructor for each of his pupils that passes an examination successfully.

W. H. also writes concerning the same subject. He is not surprised that the Board of Examiners should be dissatisfied, but he is that so many candidates should fail. He does not think the time allowed for the last Preliminary examination insufficient, or the questions unsuitable, the examination being meant for a test to prevent unsuitable persons from passing, who would be unable to succeed in future more difficult examinations. He thinks it would be a sad thing for young men to be drawn into the business by the simplicity of the Preliminary when their capabilities were altogether insufficient for the Minor. *W. H.* is of opinion that legislation to the effect that no apprenticeship to a chemist and druggist or pharmaceutical chemist, should be legal before the applicant for apprenticeship is registered as a student of the Pharmaceutical Society, would be a great boon to the student.

"A Medical Student."—(1.) We believe that Duncan's preparation is a weak solution of chloroform in spirit, made direct from alcohol and chlorinated lime. Its strength is about the same as the B. P. preparation, but it has a mild odour and flavour. (2.) In the best houses it is now customary to put in sp. chloroformi.

SULPHYDRATE OF CHLORAL.

BY M. H. BYASSON.*

If anhydrous chloral be submitted to a current of dry sulphuretted hydrogen, at ordinary temperature, the gas is absorbed; and if the current be sufficiently rapid, there is a sensible amount of heat produced. In a short time the liquid anhydrous chloral becomes nearly solid; and in order to complete the reaction it is necessary to raise the delivery tube so as to be level with the surface. At the end of about twenty-four hours the reaction is terminated. The substance formed is completely solid, white, but presenting on its surface some portions coloured reddish-yellow. By purifying this substance, first by distillation, and afterwards by crystallization from ether or absolute alcohol, pure sulphydrate of chloral is obtained, presenting the following characters:—It is white, has a very disagreeable odour, and a peculiar taste, which recalls that of chloral hydrate. It crystallizes, by slow evaporation of its solution in ether, anhydrous alcohol and chloroform, either in rhomboidal plates or in four-sided right prisms. It melts at about 77° C., and boils at 123° C., under a pressure of 0·7385. It evaporates similarly to camphor, and its vapours will darken moistened paper impregnated with a soluble salt of lead at a great distance. It is soluble in all proportions in anhydrous alcohol, ether, and chloroform. In the presence of water it is slowly decomposed, with a deposit of sulphur, the formation of sulphuretted hydrogen, which is given off, hydrochloric acid and chloral hydrate, which are found in the water, and a small quantity of a liquid which is deposited and has the appearance of tetrachloride of carbon. It is certain that in the presence of water the reaction is very complex, because the sulphuretted hydrogen exercises its reducing action upon the compound $C_4HCl_3O_2$, †as is shown by the deposit of sulphur and the formation of hydrochloric acid and chloride of carbon.

Under the influence of the hydrated alkalies or solution of ammonia, the reaction in the cold is rapid; the liquid is coloured yellowish-brown, and chloroform is deposited. The solution contains sulphydrate of sulphide of the alkaline metal and formiate, and chloride of the same base. This reaction, analogous to that presented by chloral hydrate, and in which the formation of the chloride is secondary, may be represented by the following equation:—

$$C_4HCl_3O_2,2HS + 2\,(KO,HO) = C_2HCl_3 + C_2HKO_4 + KS,HS + 2HO.†$$

Submitted to the action of concentrated nitric acid, sulphydrate of chloral oxidizes rapidly, the disengagement of nitrous vapours is intense, and the reaction should be practised upon small quantities at a time. Sulphuric acid is found in the liquid, and trichloracetic acid, the presence of which may be easily shown in the production of chloroform by the addition of potash, and which the author has isolated by distillation. This reaction may be expressed by the following equation:—

$$C_4HCl_3O_2,2HS + 4(NO_5HO) = C_4HCl_3O_4 + 2(SO_4H) + 3NO_2 + NO_4 + 4HO$$

Concentrated sulphuric acid has no marked action in the cold; with heat there is production of anhydrous chloral, disengagement of sulphuretted hydrogen and sulphurous acid, and deposit of sulphur.

By oxidizing this substance carefully with nitric acid, adding chlorate of potash at the end of the reaction, and then estimating the sulphuric acid produced as sulphate of baryta, it was found as the mean of three analyses that 0·50 grams gave 0·635 grams of sulphate of baryta. This was thought sufficiently near to the calculated number, 0·642, to justify, when taken with the preceding reactions, the formula $C_4HCl_3O_2,2HS$. It will be seen that the formula of the sulphydrate is that of the hydrate, with the water replaced by sulphuretted hydrogen.

This compound being decomposed by water or alcohol containing water, its administration is difficult. Quantities varying from 0·20 gram to 0·60 gram, in solution in ether, were injected into guinea pigs. The effects noticed were a diminution of temperature of about one degree; muscular relaxation with peaceable slumber for about two hours; no notable diminution of sensibility, and a slight acceleration of the heart's action. After the slumber the animal returned rapidly to the normal state.

STUDY.

BY W. WILLMOTT.

(*Concluded from page* 1027.)

We all know what study has done and is doing in relation to progress. Mark how swiftly we are borne over land and sea, and how ingeniously we are carried upwards through the thinner medium which surround the earth.* And then by the aid of study we find ourselves contemplating with clearness the starry universe and calculating the movements of the heavenly bodies with marvellous accuracy; whilst, on the other hand, we are seen boring through the crusts of the earth and its varied formations down to the primary granite beyond which no human ken shall ever penetrate. So that in whatever direction we proceed, there has the talisman study enthroned its power and built for all time "a local habitation and a name."

But study, like everything else, may be abused. It may be injudiciously directed on the one hand, or it may be too zealously pursued on the other. We must direct our thoughts judiciously, or we may degenerate into those egregious aberrations of intellect which invest everything with a morbid idealism. Let us by all means rise superior to this, and rely upon something higher and better for improvement and instruction.

But study may be too zealously pursued. It may be pursued to the neglect of the ordinary duties of life, or to the total overthrow of the very source from whence it flows. Sir Humphry Davy was a remarkable example of the former assumption. So zealous was his temperament, and so devoted was he to the wonders of his laboratory, that he affected not to have time enough for the necessary routine of the toilet. The consequence was he spared himself those ordinary lavations which become invested with such paramount importance in the plentiful application of soap and water; and in order, as he thought, to save time (so it is said) he was wont to

* *Vide* recent experiments.

put on his clean linen over that, whether much or little, which he happened at the time to be wearing. I believe Sir Humphry has been known to increase the amount in this way to as many as five shirts and five pairs of stockings! We are told that on the very rare occasions when he divested himself of his superfluous garments, he caused infinite perplexity to his less intimate friends, who were quite at a loss to account for his rapid transition from a state of corpulency to that of tenuity. But Sir Humphry Davy is not the only example of this kind I could mention. I am myself acquainted with a rapidly rising candidate in the field of Natural History who is so absorbed in his studies that respect for personal neatness and adornment of the most ordinary character is quite out of the question. The consequence may be better imagined than described. Men of science and others should endeavour to avoid anything like an approach to so great a mistake as this.

Again. Study may be pursued to the total disorganization of those mental phenomena which are called into play by its adoption. We deeply regret that such men as Buckland and Miller, in their earnest desire to unite Science with Faith, conjointly with the intense, though sad, conflict which the task apparently engendered, should furnish examples of this possible contingency. But so it is. Their noble, though, perhaps, mistaken efforts were past endurance; and now, far away in "that undiscovered country, from whose bourne no traveller returns," these earnest seekers after knowledge and goodness rest from their labours, and enjoy true liberty in acquaintance with that great and imperishable secret which awaits us all.

If we examine the constitution of the human mind, it will require no great perceptive ability to comprehend that a constant and excessive call upon its various faculties individually or collectively *must* tend to overthrow that due balance which is normally the sum of all its parts. Hence we are not surprised that, where imagination becomes an element of study in a highly organized capacity, the result should occasionally culminate in so sad an alternative. Stern and practical, indeed, must that man be who can look unmoved on a mind overthrown! The caution conveyed by such a possibility is too obvious to need comment.

So far, then, my remarks have partaken of a general character; but I must not overlook that special aspect of my subject which, as will be rightly supposed, comes forcibly home to my mind. The grand purpose of our lives,—we who are known as chemists, druggists, pharmaceutists, medicine-men or apothecaries, as the case may be,—is *pharmacy*. Probably no sentiment or thought calculated to urge on the student of pharmacy to the attainment of the highest point offered by his profession has been omitted in the pages of the Pharmaceutical Journal. With much eloquence and force has the subject of study been laid before the reader, and with still greater earnestness of purpose has its many advantages been dwelt upon and explained. We must so direct our thoughts that whilst we ascend to the height required, we shall detract nothing from our merits as men engaged in the daily routine of trade and commerce. The stern, practical realities of life must not be swallowed up by the grandeur of profitless and mistaken ambition. There is the counter before us, and to that counter, day by day, with steady and unwearying perseverance, must our efforts be directed. There is nothing between this and absolute failure in the hard, dry details of pharmacy.* Yet even here knowledge acquired by study will not be unavailable as auxiliary to the end in view. Time will come, no doubt, when the title indicating "the right man in the right place" will have a certain comfortable relation to the pocket which will admit of no denial. In this direction most certainly is the stream rapidly tending, and well will it be with us if we follow it closely and persistently whithersoever it goes.

I have already pointed out the possibility of disaster from too great a call upon those faculties which have for their physical basis the brain and its immediate connections; but to ourselves, as pharmaceutists, a result such as this could scarcely happen from a too earnest endeavour to gain distinction or fame. The possible mischief to us does not lie here. On the contrary, the sciences of chemistry, botany, pharmacy and materia medica, so far as the latter may with accuracy be considered sciences, are all excellent studies, and healthful and invigorating to the mind; but there is some danger lest, in the spiritless monotony of our too quiet "pharmacies," (all exceptions duly granted), the highly wrought and over-sensitive brain may stumble awkwardly against the miseries of *ennui*.† To battle with the hour during successful moments is easy; but to wrestle with Time under a heavy sense of his everlasting presence, and in the face, perhaps, of untoward circumstances, is not devoid of risk to the imaginative and thoughtful mind. Out and away, we may "kill time," so to speak, without much harm accruing; but there, "where we have garnered up our hearts," too often old Time, like the clock on the stairs, seemeth to say incessantly, "For ever!—Never! — Never! — For ever!" ‡ This possible source of mischief has not been overlooked by our ablest pharmaceutical thinker, who bravely and significantly addresses his fellow-workers as follows:—"Cultivate a cheerful frame of thought; do not scent mistakes which may never happen, nor anticipate imaginary dangers. Hope, next to knowledge,

* It is to be hoped, however, that this adherence to the counter will never render us amenable to the literary, but withal harmless, castigations of 'London Society.' "I do not know what it is," says a writer in that gorgeously conducted publication,—"the national habit of drinking beer, perhaps, or the climate, or the Metropolitan Railway, or something eminently British,—but Marshall and Snellgrove's young men, and *id genus omne*, in their hours of relaxation, are 'uncertain, coy,' and utterly devoid of *abandon*. They are stiff, wooden, impassible. They cannot shake off the shop. 'What's the next article?' is for ever trembling on their tongues, and when in repose, they turn their feet out, as though that eternal counter was still in front of them."

† Sir Benjamin Brodie, in his 'Autobiography,' speaks of "the degradation of mind which *ennui* necessarily produces."

‡ The misery that may be occasioned by a recognition of the presence of time is well set forth by the presumed happiness of the opposite condition, when "time shall be no more." "You might heap together words," says an eminent divine, "and tax the imagination to the utmost in order to delineate the glories of the New Jerusalem, with its streets of gold and its walls of precious stones, and its palaces, lit not by sun or moon; and you might outstrip all that poets have ever done in your picture of the unutterable calm of the rest of the redeemed, when congregated around the glassy sea; but in no way could you so magnify their happiness, in no way so exalt my conception of their unparalleled joy, as by telling me that they are *insensible to the lapse of time*."

is the best armour for that life's battle which we all must wage."

To conquer books with a view to examination is one thing, and by no means difficult to the determined man; but it still remains for us to learn that our victory does not end here, but that, *vincit qui se vincit*,—he conquers who conquers HIMSELF.

Much more I might have written, but here I lay down my pen, and pause. Not, however, without an increased assurance that by the right application of judicious study, we may rise to those true delights which, even in the midst of evil, are ever promised and awarded. An end like to this must sufficiently encourage, as it will surely justify, the zeal expended in its attainment. Let us, therefore, use and rightly apply the endowments we possess for the advancement of ourselves and others, ever recognizing in all things the wondrous majesty of HIM in whom must centre the attributes of mind, and to whom all thought is known from the foundation of law and order in the material world.

King's College Hospital, June, 1872.

GUN COTTON AND ITS PREPARATIONS.

BY CHARLES H. MITCHELL.*

A number of experiments were tried, with a view of ascertaining the relative proportions of cotton and acids, together with the proper time for maceration necessary to produce a cotton which should combine the largest yield with the highest explosive power and solubility. The following formula was at length adopted:—

Raw Cotton	2 parts.
Carbonate Potassa	1 ,,
Distilled Water	100 ,,

Boil for several hours, adding water to keep up the measure; then wash until free from any alkali, and dry. Then take of—

Purified Cotton	7 oz. av.
Nitrous Acid,† s.g. 1·42	4 pts.
Sulphuric Acid, ,, 1·84	4 ,,

Mix the acids in a stone jar capable of holding two gallons., and when cooled to about 80° F., immerse the cotton in small portions at a time; cover the jar and allow to stand four days in a moderately cool place (temp., 50° to 70° F). Then wash the cotton in small portions, in hot water, to remove the principal part of the acid; pack in a conical glass percolator, and pour on distilled water until the washings are not affected by sol. chloride barium; drain and dry. Yield, 11 oz. av.

This cotton is perfectly white, of a harsh, gritty fibre, very explosive, leaving scarcely any ash, soluble in ether, ether fortior, acetic ether, glacial acetic acid, and in mixture of alcohol and ether, varying from 1 part ether to 3 parts alcohol to pure ether itself. If a cotton superior to this is desired, it may be obtained by treating this cotton with an additional proportion of the mixed acids, washing and drying as before. The cotton gains about one per cent. in weight, becomes perfectly soluble, and is so free from any ash as to scarcely scorch a sheet of white paper it may be burnt on. Both this and the previous gun cotton may be ignited on gunpowder without exploding it. The advantages claimed for this cotton over that of the U. S. P. are that it is perfectly soluble, very explosive, cheap, its manufacture is much more easy, requiring but little time and attention, and turning out a superior product with large yield and less cost.

The subject of collodion next claims our attention, it being the most important pharmaceutical preparation of gun cotton. The applicability of gun cotton in ethereal solution to the dressing of wounds, inflamed surfaces, etc., was first made known by Dr. Horace Maynard, of Boston. Its valuable properties soon commanded attention, and at once supplied a want long felt in the medical profession. No better formula for collodion can be found than that of the U. S. P. Using the cotton prepared as before mentioned, it left nothing to be desired.

Collodion can also be made the vehicle for other medicines. Those remedies which are used externally, of course, can only be administered in this manner. Having made a number of experiments on this subject, I present the following formulæ, several of which I think are new:—

STYPTICS.

Styptic Collodion.

℞ Tannin	℥ ij
Stronger Alcohol	fl. ℥ iv
,, Ether	fl. ℥ xij
Soluble Cotton	ʒ j ℈ ij
Canada Balsam	ʒ j

Introduce the cotton into a suitable bottle, pour on it 2 fluid ounces of alcohol, shake well; then add 10 fluid ounces of the ether, and agitate frequently until dissolved. Dissolve the tannic acid in a mixture of the remainder of the alcohol and ether, mix with the first liquid, add the balsam, allow to stand until clear; then pour off.

Collodion with Sesquichloride of Iron.

℞ Sesquichloride of Iron . . .	℥ j grs. iv
Stronger Alcohol	fl. ℥ iv
,, Ether	fl. ℥ xij
Soluble Cotton	ʒ j grs. iv

Into a suitable bottle introduce the cotton, pour on 2 fluid ounces of the alcohol, and shake well; then add the ether, and agitate frequently until dissolved. Dissolve the sesquichloride of iron in the balance of the alcohol; mix with the prepared collodion.

ANODYNES.

Collodion with Aconite.

℞ Powdered Aconite Root . . .	℥ ij
Ether	fl. ℥ vj
Soluble Cotton	ʒ j grs. iv
Stronger Alcohol	q. s.

Mix the ether with 2 fluid ounces of alcohol, moisten the aconite with one fluid ounce of this, pack in a percolator and percolate with the balance, pouring on sufficient alcohol to recover 8 fluid ounces, in which disolve the cotton.

Collodion with Belladonna.

℞ Powdered Belladonna Root . .	℥ ij
Ether	fl. ℥ vj
Alcohol	q. s.
Gun Cotton	ʒ j grs. iv.

Mix the ether with 2 fluid ounces of alcohol, moisten the belladonna with 1 fluid ounce of this, pack in a percolator and percolate with the balance, pouring on sufficient alcohol to recover 8 fluid ounces, in which dissolve the cotton.

* From an Inaugural Essay by the Author.

† Nitric, saturated with nitrous acid.—*Ed. Amer. Journ. of Pharm.*

Antiseptics and Disinfectants.

Collodion with Carbolic Acid.

℞	Carbolic Acid	ʒj
	Ether	fl.℥vj
	Stronger Alcohol	fl.℥ij
	Gun Cotton	ʒj grs. iv.

Dissolve the gun cotton in the ether and alcohol mixed, and then add the carbolic acid.

Collodion with Sulphocarbolate of Zinc.

℞	Sulphocarbolate of Zinc . . .	ʒj
	Ether	fl.℥vj
	Stronger Alcohol	fl.℥ij
	Gun Cotton	ʒj grs. iv.

Introduce the cotton into a suitable bottle, add 1 fluid ounce alcohol, shake well; add the ether, and agitate frequently until dissolved. Dissolve the zinc salt in the balance of the alcohol, and mix with the prepared collodion.

Collodion with Thymol.

℞	Thymol	ʒj
	Ether	fl.℥vi
	Stronger Alcohol	fl.℥ij
	Gun Cotton	ʒj grs. iv.

Dissolve the cotton in a mixture of ether with part of the alcohol, dissolve the thymol in the balance of the alcohol, and mix.

Stimulants in Cutaneous Diseases.

Collodion with Iodide of Mercury.

℞	Mercuric Iodide	ʒj
	Potassium Iodide	ʒss
	Alcohol	fl.℥iv
	Ether	fl.℥iv
	Gun Cotton	ʒj grs. iv.

Triturate the iodides together in a mortar, add the alcohol boiling, and rub until they are completely dissolved. Then add the gun cotton, lastly the ether, and agitate frequently until the cotton is all dissolved.

Stimulants and Rubefacients.

Collodion with Arnica.

℞	Powdered Arnica	℥iv
	Ether	fl.℥xij
	Stronger Alcohol	q. s.
	Gun Cotton	ʒij grs. viij.

Mix the ether with 4 fluid ounces alcohol. Moisten the arnica with sufficient of this, pack in a percolator and pour on the balance, following with alcohol until 16 fluid ounces of tincture have been recovered; to this add the cotton, and agitate frequently until dissolved.

Collodion with Capsicum.

℞	Ground Capsicum	℥iv
	Ether	fl.℥xij
	Stronger Alcohol	q. s.
	Gun Cotton	100 grs.

Proceed as in collodion with arnica, recovering 16 fluid ounces of tincture, in which dissolve the gun cotton.

Collodion with Mezereon.

℞	Ground Mezereon	℥iv
	Ether	fl.℥xij
	Alcohol	q. s.
	Gun Cotton	128 grs.

Mix the ether with 4 fluid ounces of strong alcohol, and in this allow the mezereon to macerate one week. Drain, pack tightly in a conical percolator, pour on the separated liquid, and follow with enough alcohol to recover 16 fluid ounces of tincture, in which dissolve the cotton.

Collodion with Savin.

℞	Powdered Savin Leaves . . .	℥iv
	Ether	fl.℥xij
	Alcohol	q. s.
	Gun Cotton	grs. 128.

Proceed in same manner as collodion with capsicum.

Collodion with Black Pepper.

R.	Ground Black Pepper . . .	℥iv
	Ether	fl ℥xij
	Alcohol	q. s
	Gun Cotton	128 grs

Proceed in the same manner as in collodion with capsicum.

Vesicants.

Collodion with Cantharides.

R.	Powdered Cantharides . . .	℥iv
	Ether	fl ℥xij
	Stronger Alcohol	q. s
	Gun Cotton	80 grs

Moisten the cantharides with a small portion of the ether, and pack in a conical percolator. Then pour on the balance of the ether, mixed with 4 fluid-ounces alcohol, and follow with enough alcohol to recover 16 fluid ounces, in which dissolve the gun cotton.

These collodions can be used as substitutes for many of the officinal plasters, having the advantage of occupying a small bulk, ready adaptability to any surface, and powerful therapeutic action.

I have endeavoured, as far as possible, to give some practical information on a branch of pharmacy of which comparatively little is known. The subject is, I think, an important one, since gun cotton and collodion occupy a high position in both medicine and the useful arts, and to its elaboration and useful application too much study cannot be devoted.—*Amer. Journ. Pharmacy.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Zinci Valerianas.—$Zn(C_5H_9O_2)_2$. Sulphate of zinc and valerianate of soda are dissolved separately in hot water, the solutions mixed, and the crystals, which are deposited almost immediately, removed by straining. A few more are obtained by evaporating the liquid. The whole of the crystalline deposit is then washed and dried without heat.

$$2NaC_5H_9O_2 + ZnSO_4 = Zn(C_5H_9O_2)_2 + Na_2SO_4$$

[§ In brilliant white pearly tabular crystals with a feeble odour of valerianic acid and a metallic taste; scarcely soluble in cold water or in ether, soluble in hot water and alcohol. Its solution in hot water is not precipitated by chloride of barium. It gives when heated with diluted sulphuric acid a distillate which, when mixed with solution of acetate of copper, does not immediately affect the transparency of the fluid, but forms after a little time oily drops, which gradually pass into a bluish-white crystalline deposit.] It may be remarked that it is more than usually difficult to remove from valerianate of zinc the whole of the sulphate; and all commercial samples give a precipitate with chloride of barium. With regard to the last test, it is intended to detect admixture of butyrate of zinc, a sophistication which at one time was not uncommon.

ZINCUM.

[§ Zinc of Commerce.]

The principal ores of zinc are blende, ZnS, calamine $ZnCO_3$, and the red oxide. To obtain zinc the ore is first roasted, by which, in any case, it is converted into the oxide, and it is then heated with coke or charcoal in earthen or iron retorts of peculiar shape. The zinc distils over and condenses in the liquid form. Commercial zinc contains lead, iron, and generally traces of cadmium and arsenic. To obtain it free from impurity, the carbonate may first be prepared and this, after conversion into oxide, distilled with pure charcoal.

Zinc for chemical purposes is generally granulated by melting it and pouring in a thin stream into a quantity of cold water.

Ordinary zinc is somewhat brittle at common temperatures, but becomes malleable, and may be rolled into sheets when heated to 250°–300° F. When the temperature is further raised to a little over 400°, it becomes so brittle that it may be rubbed to powder. Although ordinary zinc dissolves in dilute acids very readily, this is not the case with the pure metal. The particles of lead which are imbedded in common zinc, form with the zinc in presence of the acid a voltaic combination in which the zinc acts the part of the positive metal, and the lead the negative. To make pure zinc or tin dissolve readily in acids, it is best to place in contact with it a piece of platinum foil; the same kind of electrical polarization is then set up, and this very greatly assists the chemical action.

MATERIA MEDICA NOTES.

BY JAMES COLLINS, F.B.S.E.

Curator of the Pharmaceutical Society's Museum.

GUM EUPHORBIUM.—Dr. E. Cosson, in an interesting note on *Euphorbia resinifera*, Berg, read before the Royal Botanical Society of Belgium, verifies the statement of Berg, that the Gum Euphorbium of commerce belongs to the species to which Berg gave the name of *E. resinifera*. Dr. Cosson found in Von Martius' collection at Brussels, a specimen of Gum Euphorbium with sufficient of the dried stems of the plant producing it to give a good idea of the plant. Probably Von Martius received these specimens from his brother, Dr. T. W. C. Martius.

The history of this acrid gum is very interesting. *E. canariensis*, L., *E. officinarum*, L., *E. antiquorum*, L., and *E. tetragona*, Haw., have each been accredited with its production; but Dr. Pereira, who examined the question with his usual critical ability, stated that only *E. canariensis* fulfilled all the requisite conditions of locality, etc.; and that he felt little hesitation in ascribing the gum to this plant. He says (Elements Mat. Med. vol. ii. pt. 1. p. 399, 1855) that the specific characters "apply to the branches found mixed with the Euphorbium of commerce. They agree with the description and figure of *Tithymalus aizoides lactifluus*, the *Euphorbia canariensis* of Plunkenet." Miller also (Gard. Dict. vol. i. art. Euphorbium) states that in looking over some Euphorbium in a shop, he "found several spines amongst it, which exactly agreed with those of that plant." Pereira found in some specimens of the gum, spines resembling those of *E. tetragona*, Haw.

But better materials led Berg to trace its origin to a new species, to which he gave the name of *E. resinifera*, and described from dried remains picked out of the gum. *E. resinifera* has a stem one-third the size of that of *E. canariensis*, and stalked umbels, whilst *E. canariensis* has almost sessile flowers. Berg gives figures in 'Berg und Schmidt, Darstellung und Beschreibung sämmtlicher in der Pharmacopœia Borussica.' The gum contains 20 per cent. of an acrid principle Euphorbin ($C_{26}H_{22}O_2$), so acrid indeed that in the collection of the gum the fingers become excoriated if brought into contact with it, and it is the practice to cover the mouth and nostrils to avoid the excessive sneezing which would otherwise ensue. The best general account of the production of this gum is that of Jackson, in his 'Account of Morocco.'

Dr. Cosson has also compared the various materials he has with a growing plant at Kew (which has not yet flowered), sent by Mr. F. Cartensen, the English Consul at Mogadore. If the history of this plant can be satisfactorily attested as being the species actually producing the gum, its flowering will be looked to with some degree of interest, as the question can then be set completely at rest.

CINCHONA ROSULENTA.—Mr. Howard has recently cleared up another doubtful point in the cinchona question. He has described and figured in the 'Bulletin de la Société Botanique de France' a new species, named *Cinchona rosulenta*, a native of Ocana, in New Granada. The vernacular name appended to the specimens of this plant, which were collected by Purdie in October, 1845, is "Quina de la tierra fria." *C. rosulenta* is very close, both in appearance and chemical composition, to *C. succirubra;* the bark, however, has a more roseate hue, and the leaves approach *C. ovata*, the nerves, however, being more rigid and prominent. Mr. Howard identifies this species with the *Quinquina rosé* d'Ocana, of M. Delondre, a figure of which is given in that author's 'Quinologie;' also with M. Rampon's *Quinquina à quinidine*, described in Dr. Planchon's 'Des Quinquinas;' and also with Dr. Wittstein's '*Peseudo regia.*'

This bark has long been known in French commerce under the name of "Quina rosé," and we are grateful to Mr. Howard for thus clearly settling its synonymy, and giving it a botanical position.—*Journal of Botany.*

PURIFICATION OF WATER CONTAINING ORGANIC IMPURITIES.

BY PROF. G. DRAGENDORFF (Dorpat, Russia).

Years ago, as is well known, Scherer proposed for the purification of water, especially when it contained large quantities of organic substances, the use of a solution of a ferric salt, especially of the sulphate.

Lately, Gunning made a similar proposition, recommending ferric chloride for this purpose. The object is plainly the precipitation from the ferric salt of the ferric oxide, which carries with it organic compounds, as for instance the deposits of many mineral springs which separate from the water all, or almost all, organic impurities. There the action is mainly one of surface attraction of the hydrated oxide in solution, which is greater with the increased volume of the precipitate.

This attraction first acts only upon the substances in solution, but extends to a large portion of the suspended substances, vibriones, amœbæ, etc. The precipitate acts upon them like the coagulation of albumen in solution, which at the moment of coagulation envelopes suspended particles, that render the liquid turbid. That the freed acid at the same time changes ammonia, its carbonate, and similar substances present in such water, into less volatile compounds, removing thus ammonia compounds in case of distillation from the distillate, is a matter of course. But even the acid may in part remain free, and especially, if carbonates do not abound, be injurious. At least, if the liquid becomes concentrated during subsequent distillation, other acids, like muriatic, would be set free, thus contaminating the distillate. I think that on the whole it would be preferable to employ for the above purpose an iron compound completely free from acid. Such a one we find in the liquor ferri dialysati, the preparation of which I have mentioned in the previous article. There I remarked that the liquor cannot come in contact with well-water without decomposition. I now add, that the decomposition upon such contact with well-water furnishes hydrated ferric oxide, which is very voluminous, and therefore may be supposed extremely applicable to the precipitation of organic admixtures.

Indeed, experiments made with very turbid swamp-water showed me that liquor ferri dialysati precipitated the suspended organic impurities, the water becoming clear. Even a portion of the organic substances in solution I was able to introduce into the precipitate; but I became convinced that for the complete separation of the latter, so large a quantity of the liquor is requisite as to render its practical application impossible. The following examples may serve as illustrations:—

Experiment 1. 200 c. c. of the above water, heated to 70°-80° and mixed with 5 c. c. diluted sulphuric acid (1 : 13), used up 6·2 c. c. of a solution of potassic permanganate, of which 6·0 c. c. were required to decompose 10 c. c. of a solution of oxalic acid, containing 0·398 grms. to the litre, to the extent of producing a reddish colouration, lasting about two minutes.

Experiment 2. 300 c. c. of the same water were mixed with 2 c. c. of liq. ferri dialysati, containing 1·5 per cent. hydrated ferric oxide, submitted to rest in a closed vessel for two days, when 200 c. c. of the clear supernatant liquid were withdrawn with a pipette, titrated with permanganate, of which 5·6 c. c. were used.

Experiment 3. A mixture of 300 c. c. of the same water with 3 c. c. liq. ferri dialysati: 200 c. c. of the clear supernatant liquor used up 4·2 c. c. of permanganate.

Experiment 4. A mixture of 300 c. c. of the same water with 4·5 c. c. liq. ferri dialysati: 200 c. c. of the clear supernatant liquor used 3·8 c. c. of permanganate.

The used of ferric chloride and sulphate also furnished no more favourable result, for even then part of the original organic substances in solution escaped precipitation.—*The Chicago Pharmacist.*

SOME CONSTITUENTS OF ERICACEOUS PLANTS.*

BY JEFFERSON OXLEY.

Of this order, *Uva ursi* and *Chimaphila umbellata* have, upon examination, been found to contain arbutin, urson and ericolin. Thinking it of some interest to know if these principles are alike common to other plants of the same order, *Gaultheria procumbens* and *Epigæa repens* were submitted to examination.

From two pounds of *Gaultheria*, as usually found in market, after removing the larger stems, the remaining leaves and smaller stems weighed one pound and six ounces, showing a loss of 31 per cent. Garbling one pound and a half of *Epigæa repens* in the same manner, one pound of leaves and small stems remained, indicating a loss of 33 per cent.

Reduced to a convenient powder they were digested with water during several hours, strained and expressed, and a second time submitted to like treatment. Upon drying the residue, the *Gaultheria* weighed twelve ounces, a loss of 45 per cent. *Epigæa repens* weighed ten and a half ounces, a loss of about 34 per cent.

The infusions were treated with neutral acetate of lead, the filtrates with subacetate of lead, and filtered. The resulting solutions were almost free from colour, being a light yellow. The lead was removed with sulphuretted hydrogen, the solutions filtered and heated to remove excess of hydrosulphuric acid. After concentrating and treating with ammonia to neutralize the acetic acid present, then with animal charcoal, and washing with cold water, the filtrates were reduced by heat, and set aside to evaporate spontaneously. After several days, crystals not appearing, a portion was separated and treated with alcohol, leaving a large per cent. of insoluble extractive matter. The alcoholic solutions were allowed to evaporate to a syrupy consistency, but without the formation of crystals.

At this point the extract of *Epigæa repens* was of a deep reddish-brown colour, very much resembling liquorice in odour and taste. On adding sulphuric acid to a dilute solution of this extract, no precipitate was produced indicating the absence of glycyrrhizin

The extracts were dissolved in water, treated with animal charcoal, washed, and the filtrates set aside to evaporate, but failed to yield crystals. The charcoal used in the latter case was digested with alcohol. The alcoholic solutions in each case had a slight colour; that from *Epigæa repens* light yellowish-brown, from *Gaultheria* light green. Upon evaporation these solutions yielded a small crop of crystals.

The evaporation was continued for several days, with the hope of a large yield; upon examination the crystalline structure was found in a great measure lost. The yield was too small to apply the various tests for arbutin. Jungmann's test* was applied. A dilute aqueous solution rendered alkaline with ammonia, produced, on the addition of phosphomolybdic acid, a blue colour.

A portion of the reserved aqueous extract was submitted to like treatment, producing the blue reaction due to arbutin; the formation of crystals and the reaction with phosphomolybdic acid warrant the conclusion that arbutin is present in each of the plants under consideration. However, it seems present in a much smaller proportion than in *Uva ursi* or *Chimaphila umbellata*, and separated with much more difficulty.

The above extracts were dissolved in a dilute solution of sulphuric acid and distilled, the distillates possessing a peculiar and rather agreeable odour, indicating the presence of a volatile principle liberated by the action of the acid. The distillates possessed an acid reaction, due, no doubt, to the acetic acid present in the lead salt used in the early part of the process. Neutralized with bicarbonate of soda and redistilled, the odour remained intact, and the distillates possessed a slight acid reaction. Neutralizing the residue with nitric acid, treating with sesqui salts of iron, produced in each a red colour, which was removed upon the addition of a strong acid. Nitrate of silver and protonitrate of mercury gave precipitates which, by heat, liberated the metals in the case of *Epigæa repens*, but not so in that of *Gaultheria*. With a mixture of alcohol and sulphuric acid added, each gave an odour characteristic of acetic ether, indicating acetic acid. The reaction with the solution from *Epigæa repens* indicated the probable presence of formic acid.

An infusion of *Uva ursi* was also distilled in the presence of sulphuric acid. The odour of the distillate was found, on comparison, to be quite similar to those referred to, that from *Gaultheria* varying somewhat, perhaps owing to the volatile oil.

A portion of the dried leaves remaining from the infusions was treated by percolation with alcohol; the resulting tinctures were of a deep green colour, that from *Gaultheria* possessing a beautiful emerald hue. Allowing the tinctures to evaporate spontaneously, the residue was put upon a filter and washed with alcohol to remove the chlorophyll: that from *Epigæa repens* parted with this colouring matter more readily than *Gaultheria*; urson was not obtained in a pure state, but sufficiently so to be sublimed in a test tube. The action of reagents

* From an Inaugural Essay by the Author.

* 'American Journal of Pharmacy,' 1871, p. 207.

could not be brought to bear upon the principles isolated, owing to the presence of chlorophyll, but as far as examined they agree with urson.

A portion of the precipitates obtained by treating the infusions with acetate of lead was freed from lead. The presence of tannin in the solution was indicated by the production of precipitates with solutions of gelatine, salts of iron (black), tin, mercury, copper, silver (a liberation of the metal by heat), and by the deep red colour with alkalies. After freeing the solution from tannin by gelatine, several reagents indicated the presence of gallic acid. After evaporating a portion of the solution with some sand to dryness, and subliming in Mohr's benzoic acid apparatus, pyrogallic acid was not obtained; therefore gallic acid is not present, but a principle having similar reactions. Trommer's test gave reactions indicating grape sugar.

A concentrated infusion of the leaves was precipitated by alcohol, and the dried precipitate was found to contain gum.

The stems and the leaves of *Gaultheria* and *Epigæa*, when distilled with water, did not yield chimaphilin, discovered by Mr. Samuel Fairbank. In the distillate from the stems of *Chimaphila umbellata* orange red crystals of chimaphilin were obtained, and the yellow aqueous distillate yielded more of the same crystals when agitated with ether.

Among the organic constituents of *Gaultheria* and *Epigæa* have been found, by this examination, arbutin, urson, ericolin, tannic acid, and a principle analogous to gallic acid, formic acid (in *Epigæa*), grape sugar, gum and colouring matter.—*American Journal of Pharmacy.*

THE MANUFACTURE OF ATTAR OF ROSES IN TURKEY.

The art of extracting the odoriferous liquids from the rose,—the favourite flower of all civilized nations,—is very old. The ancient Greeks and Romans, the Egyptians and the Hindoos, were acquainted with rose-waters, but the oil of roses, that most precious part of the blossom of the flower, which alone gives the delicious flavour, and which is to be found only in extremely smallest quantities in the leaf cells of the blossom, was unknown to the Greeks and Romans. The preparation of it was the invention of the old Hindoos, and even at the present time a great quantity of the oil is produced in India. Ghazimpoor on the Ganges is now the most important place where this dear and precious ethereal oil is manufactured. But rose-waters are produced in other parts of the world in as great quantities as there. The Indian oils and rose-waters are consumed in that country, where these perfumes are in as much favour and used as extensively as the Eau de Cologne with us. It is most remarkable that, of the large quantity of rose-oil which England consumes, none of it comes from India. The produce of the "Shiraz plain" in Persia is also very insignificantly represented in the European market. It has been noticed that Persian rose-water is not exported for the European trade, and that rose-oil is not produced there but imported from India. The famous rose districts of "Medinet Fayum," south-west from Cairo, are only of advantage to Egypt; and the once important rose-oil produce of Srinagars is in decay.

The rose-oil which Europe consumes at present comes almost exclusively from the southern slopes of the Balkan, where, in some one hundred and fifty places, the ingathering of the rose blossoms and the manufacturing of the rose-oil takes place. The quantity of oil which is produced in the south of France is very unimportant as compared with the quantity of the Turkish produce.

The most important Turkish districts where this valuable article is produced are Tchirpan, Philippopolis, Carlova, Yeni-zaghra, and Kizanlik: this last is the most important of all. The produce of this place alone amounted in 1857 to 199,000 midkals or metticals (1 mettical equal to 4·79 grams). Now the quantity is estimated at 500,000 metticals.

Professor Dr. Hochsteller, from the Vienna University, in his most interesting reports to the Geographical Society at Vienna, of his travels through Roumelia in the summer of 1869, has given very important data of the produce of oil at Kizanlik which he gathered chiefly from Mr. Julius Kasselmann, settled there. These data may serve to remove many incorrect statements published on the subject.

The roses planted in the basin of Kizanlik have light red blossoms. They are planted in rows like the vine. Sometimes roses and vines are planted intermingled on the same plot. The most important species of roses planted there are *Rosa damascena*, *R. sempervirens*, and *R. moschata;* the first of these is also planted in the south of France; the last mentioned, which has a slight musk flavour, gives the chief material of the produce of the Indian rose-oil.

The roses are gathered in their blossom state during the month of May, and are subjected to distillation together with their green calyx leaves. The still consists of a tinned copper boiler from which a pipe runs into the cooling tub. In every boiler are placed 50 okes* of water and 10 to 20 okes of roses, and the heating takes place over an open fire. The mass is boiled for two hours, the first part of the distilled fluid is put again into the boiler; the fluid, then condensed, is gathered into bottles with broad bottoms and strait necks. Water and oil distil over at the same time, the latter of course floating on the surface.

When there is a layer of oil of the thickness of a finger, it is removed. This is done by a funnel-shaped spoon with a very thin opening at the top which permits a passage to the water but not to the oil. 5000 lb. (German weight) of roses gives by careful distilling 1 lb. of oil.

The so-called freezing degree, that is, the degree of temperature when the separation of the solid parts takes place, varies with the oils of Kizanlik between 8 to 16 degrees Réaumur, equal to 50 to 68 degrees Fahrenheit. The best oils get solid or stiff at these temperatures; they come from the colder mountain districts, whereas the oils from the warmer localities get solid at 12 to 16 degrees Réaumur equal to 59 to 68 degrees Fahrenheit. These oils, marked strong oils, have a less delicate flavour, and are preferred by ignorant traders.

It is evident that such a valuable substance as the rose-oil is very much exposed to adulteration. The adulteration takes place most extensively at the home of the oil, where also the substance for adulteration is produced on a large scale. This article, also an ethereal substance, is called in India "rosia-oil," in Egypt "idris-oil," and in England "ginger-oil." It is distilled from species of *Andropogon* and *Cymbopogon*.† The idris-oil is sometimes called "geranium-oil." Among the data furnished by Mr. Kasselmann is one that the distillers often adulterate the rose-oil with geranium-oil which is imported from Alexandria. This is but idris-oil exported from Bombay.

The rose-oil is exported in round tinned copper bottles called "kunkoumas," which, when filled, are closed by soldering. The price on the spot per German pound is 120 to 125 thalers.

To the above particulars, which are translated from the Vienna *Neue Freie Presse*, Mr. Blunt, Her Majesty's Vice-Consul at Adrianople, in a recent report,‡ adds some further information as to the manufacture of attar of rose in that district. He says that since his last re-

* Oke = 1200 grams.

† *Cymbopogon* is synonymous with the genus *Anatherum;* the latter is the name used. Both *Anatherum* and Andropogon belong to the Order *Gramminaceæ* (section *Andropogoneæ*).

‡ Reports from Her Majesty's Consuls, No. 1 (1872), p. 266.

port in 1866 the cultivation of the rose plant and the manufacture of attar have been vigorously carried on by the inhabitants, principally Bulgarian and Turkish peasantry, but only with partial success as regards the quantity yielded; for during the last five years (1867–71) the average yield of the crop each year has not exceeded 400,000 midkals or about 600,000 drachms, whereas the yield of an average crop should be about 825,000 drachms.

This falling off in quantity Mr. Blunt considers not to be the result of a decline in the cultivation of the rose, for he has been assured by producers that the area of plantations has been annually enlarged and improved in Kizanlik and elsewhere. It is mainly attributed to atmospheric influences: one year the flowering season was retarded by sudden frosts; in another the crop was reduced by blight and caterpillars, and so on.

The crop for the year 1871 looked very promising indeed in March, but a sudden frost in the budding season in April, and hot and dry weather in May, very considerably reduced its yield, and deteriorated the quality of the oil extracted.

It is estimated that the total quantity of oil distilled in 1871 amounts to barely 360,000 midkals, equal to 540,000 drachms. Of this, 305,000 midkals or 457,500 drachms had at the time of the report (October, 1871) already been exported, principally to the United Kingdom, United States of America, France and Germany. The stock in hand for exportation was about 120,000 drachms, including 37,000 drachms from the crop of 1870.

The average price of attar in 1871, free on board at Gallipoli, including 1 per cent. customs duty, was quoted at 15 piastres per midkal, equal to about 2*s.* 9*d.* per $1\frac{1}{2}$ drachm, the pound sterling equalling 110 piastres.

The following table gives the average cost of Adrianople attar, free on board, in 1867–70:—

FREE ON BOARD AT GALLIPOLI.

Year.	Cost in Turkish Money, and per Turkish Measure. Per Midkal. Piastres.	Cost in English Money, and per English Measure. Per $1\frac{1}{2}$ dram. *s.* *d.*	Including Rate of Customs Duty levied, *ad valorem.* Per cent.
1867	20	3 $7\frac{1}{2}$	5
1868	16	2 11	4
1869	$17\frac{1}{2}$	3 2	3
1870	16	2 11	2

A sketch of the apparatus used in the process of manufacturing the attar, drawn by a Turkish engineer of the vilaet, and kindly furnished by his Excellency Atta Bey, ex-Governor of the province of Philippopolis, accompanies Mr. Blunt's report.

With reference to the amount of the several taxes which Government levy on the manufacture and exportation of attar, Vice-Consul Blunt says that besides the tenth part of the produce, or its money value, which Government annually levy, an internal duty of 8 per cent. *ad valorem* is also levied on what is sold for home consumption.

The Customs duty on attar, which is exported to foreign countries, is 1 per cent. *ad valorem.*

Thus Government take 11 per cent., including tithe, on attar which is exported, and 18 per cent., also including tithe, on what is consumed in the country.

A merchant wishing to export attar, on which the tithe has already been levied, generally has to deposit with the authorities at Kizanlik the internal duty of 8 per cent. on the quantity to be exported: this is repaid to him on his producing, within sixty days, to count from the date of the deposit, a declaration of the Custom-house at the port of exportation specifying the quantity of Turkish attar he cleared and shipped. If this declaration, called "Ilmi-haber," is not produced within the sixty days, the deposited duty is forfeited, as the attar is then looked upon as being for internal consumption.

DISINFECTANTS.

A commission appointed by the French Academy to investigate the relative merits of various disinfectants for use in hospitals where contagious diseases are treated, have made the following report as the result of their experiments:—

Hyponitrous Acid.—The members of the commission agree that the first place among agents for attacking and destroying infectious germs must be accorded to *hyponitrous* acid. Extraordinary precautions must, of course, be observed in making use of this dangerous gas; the doors and windows must be carefully sealed with gummed paper when disinfecting a room containing forty or fifty cubic yards. The materials are taken in the following proportions:—Two quarts of water, three and a quarter pounds of ordinary commercial nitric acid, and half a pound of copper turnings or filings. A stoneware vessel is employed, holding two or three gallons. The exit doors are carefully pasted up, and the room left closed for forty-eight hours. The person opening the room at the expiration of the time should be protected in some way from breathing the gas, by a suitable respirator.

Carbolic Acid.—This is cheaper, more easily used, less dangerous, and has proved equally efficacious. It is best employed mixed with sand or sawdust—one pound of acid to three pounds of an indifferent substance. The mixture, placed in earthen vessels, was used for the same purpose as the hyponitrous acid. Carbolic acid, diluted with fifteen or twenty parts by weight of water, was found useful for daily sprinkling of the floor and bedclothes.

An interesting case is mentioned in the report where neither chlorine nor hypochlorous acid was able to destroy or render odourless the gases given off from the corpses in the Paris Morgue during the heat of summer. The object was attained by dissolving a quart of liquid carbolic acid in 500 gallons of fresh water, contained in the reservoir and used to sprinkle the bodies. Putrefaction was entirely stopped.

Devergie found that water containing only one to four thousandth part of its weight of carbolic acid sufficed to disinfect a dead house, even in the hottest weather, when six to eight corpses were in it.

For fumigating linen, mattresses and other bedding with chlorine, Regnault's latest method was used, namely, one pound of chlorinated lime (bleaching powder) is sewn up in a strong bag of sail cloth, holding about a quart, and put in an earthen pot containing a quart of common muriatic acid (sp. gr. 1·15) and three quarts of water. As soon as the acid comes in contact with the chloride of lime the room is closed, and the things exposed to the action of chlorine gas for twenty-four hours; the room is then aired for forty-eight hours. Ten such earthen pots give off 500 litres of chlorine, sufficient to disinfect from twenty to twenty-five, more or less, dirty mattresses.—*Scientific American.*

A NOVEL METHOD OF COPYING MANUSCRIPTS AND DESIGNS.

A very beautiful application of science has recently been made for readily copying writings and designs, which we doubt not will receive extensive application by men of business. The invention has been elaborated by an Italian gentleman, M. Eugene de Zuccato, who has not only pointed out the way to be followed in carrying out the discovery, but has effectively completed the copying apparatus before publishing it to the world. Photography may be made to give its aid in producing the copy of the document or design in the first place, supposing the same cannot be produced direct; and from this reproduction is printed off as many facsimiles in an ordinary copying press as may be desired.

The invention consists in decomposing prussiate of potash by means of electricity, and causing it to form with iron the well-known pigment Prussian blue, by means of which the design is traced upon the paper. The apparatus is very simple and easy of explanation. A steel plate is covered in the first place with a coating of varnish, and upon this is scratched with a steel point any writing or design it is desired to copy; as the steel point has removed the varnish where it has touched the plate, the writing is of course formed of bright metal upon a varnished ground. If a design or autograph letter is to be copied upon the steel plate by photography, the metal surface is in this case coated with a solution of gelatine and bichromate, and then printed under a positive *cliché;* on washing, there will remain, in the same way as before, the writing or design in bright metal upon a ground of bichromated gelatine.

For printing, an ordinary letter-copying press is employed, the bed of which is insulated from the upper plate; so that if the two wires from an electric battery are connected, the one to the top and the other to the bottom of the machine, no current could pass until the upper and lower plates of the press were screwed together and thus brought into contact. Three or four sheets of thin copying paper are now impregnated with a solution of prussiate of potash, and while still moist the steel plate bearing the writing or design is placed upon them, and the whole put into the press. The wires of a battery are attached in the manner indicated, and the press screwed down. A current of electricity then passes from the upper to the lower plate of the press and through the moistened paper, decomposing the prussiate contained therein; the electricity can, however, pass only when there is a bright metal surface; and this occurs, as we have seen, only where the design in bright metal appears (where the steel plate is not covered with varnish); and in these places, some of the metallic iron being dissolved, there is formed prussiate of iron, or, in other words, the blue pigment known as Prussian blue. Consequently, the moist sheets of copying paper, when the electric action is set up, are stained with a reproduction of the design upon the metal plate; and as many times as the operation is repeated, so often will a batch of three or four copies be produced. As thirty seconds or a minute is sufficient for each operation, copies can in this way be easily obtained at the rate of a hundred per hour.

The patent is, we believe, the property of Messrs. Waterlow and Sons, who propose at once to offer it to the public; for in such places as the counting-house and engineer's office the apparatus will be invaluable. The electro-chemical copying press, as we believe it is termed, forms one more excellent example of science serving as handmaiden in our everyday life.—*Photographic Journal.*

QUICKSILVER.*

The long-prevailing high price of quicksilver has exercised an important influence on our mining interests, and the importance of obtaining it at low rates will be evident to all, except producers. In the production of gold and silver bullion quicksilver is an indispensable requisite, and without it our mines could not be developed, unless the ingenuity of our people could devise some suitable substitute not now known. The production of this necessary article at the cheapest possible rate is a matter of great interest to our mining population; and the many mines of this metal in California, by proper and economical working, with suitable appliances, and without combinations to keep up rates, should be able to produce and sell it at a much more reasonable price than present quotations. A low price for quicksilver would cause an increase in consumption, and of course, larger sales, requiring a greater production. It is an absolute necessity for the purposes for which it is mainly used, and for amalgamating particularly, where it is now used with a sparing hand, a more plentiful supply would be a material benefit.

The amount of quicksilver which the various mines of the world are capable of producing is very large, much larger, in fact, than is demanded for any purposes to which it is at present applied, and the only reason why it is held so high is that a few parties have control of the supply of the world. The Almaden Mine, in Spain, discovered in 1497, yielded for 250 years from 550,000 to 650,000 lb. per annum. In 1750, when the Huancavelica Mine of Peru caved in, and the supply from that source was temporarily cut off, the Almaden increased its production to about 2,016,000 lb. per annum, and has continued to yield that amount ever since. The Santa Barbara Mine, of Huancavelica, which had up to 1867 produced 80,000,000 dollars' worth of quicksilver, is now abandoned. The reasons given are its distance from sea-board, low grade of ores, and scarcity of fuel, being unable from these causes to make any profit in competition with the other great mines of the world. The Idria Mine, in Transylvania, is another of the important mines of the world, and its production is from 600 to 800 flasks per month. The ores are of a low grade. This mine is under lease from the Government.

California, among its numerous mineral advantages, possesses the broadest fields of this necessary article in the world, and by far the most prolific of its mines is the well-known New Almaden, in Santa Clara County. As it may be interesting to know the amount produced from this mine yearly, as the representative one of California, the following figures will show it, in flasks, premising that the flasks contain 76½ lb. of quicksilver. In 1851 the number of flasks produced was 23,875; in 1852, 19,921; in 1853, 18,035; in 1854, 26,325; in 1855, 31,860; in 1856, 28,183; in 1857, 26,002; from July, 1857, to October, 1858, 39,935. From that time to February, 1861, the mine was closed by injunction. From February, 1861, to January, 1862, it produced 34,765 flasks; in 1862, 40,391; in 1863, 19,564; in 1864, 46,216; in 1865, 47,194; in 1866, 35,150; in 1867, 24,461; in 1868, 25,628; in 1869, 16,898; in 1870, 14,000; and in 1871, 18,763 flasks. Total up to January, 1872, 537,176 flasks, each containing 76½ lb. of quicksilver.

The New Idria Mine, in Fresno County, produced in 1866, 6045 flasks; in 1867, 11,500; in 1868, 12,300; in 1869, 10,450; in 1870, 10,000; and in 1871, 9227 flasks. The Redington Mine, near Knoxville, Lake County, produced in 1866, 2980 flasks; in 1867, 7145; in 1868, 8700; in 1869, 5000; in 1870, 4546; in 1871, 2128 flasks.

Among the other mines whose products go to swell the gross amount are the Guadalupe, in Santa Clara County, owned in Baltimore, Md.; the Josephine, in San Luis Obispo County, owned by Barren and Co.; the Enriquita, owned by the Almaden, and the Bautista, owned by the Almaden, and now idle, both in Santa Clara County; the Pioneer is in Napa County, the Whitton is in Napa County, and there is one at Oakville. The Vallejo Mine is in Solano County; the Manhattan or Knox and Osborne Mine is three miles from Knoxville, in Lake County; the California is in Yolo, and there are several in Pope Valley, near Napa; the Abbot Mine is in Lake County; Excelsior in same county. There are several in Monterey, one of which is called the Pennsylvania, which produced a small quantity, and one owned by M'Garrahan not now being worked. There is one at Mount Diablo, Contra Costa County, which produced a small quantity, but is now in litigation. An occasional flask comes from the San Luis Obispo Mines. The Riotte and Lockhart Mine is at St. Helena, Napa County. The Phœnix, in Pope Valley, Napa County, produced in 1870, from a partial working only, 763 flasks. There is also a mine in San Bernardino County, and several recent discoveries in Napa and Lake Counties, and a

* This article, taken from an American source, appeared in the *Mining Journal* for June 15th, 1872. We reprint it as containing matter likely to be of interest to our readers.

number are spoken of, from which we hear little, in Coast Range, from up north down to San Bernardino County. The total product from all the California mines mentioned for the last three years was, according to the *Commercial Herald*, as follows:—In 1869, 36,600 flasks; in 1870, 29,546 flasks; in 1871, 31,881 flasks.

The total monthly product at present is said to be not over 3100 flasks, of which the New Almaden furnishes 1600, the Redington 600, the New Idria 600, and all others 300. The New Idria cleaned up 2000 flasks in January,—40 from the mine, and the remainder from what had accumulated inside the condensers.

Quicksilver has remained at a high rate for the past three years, and at such a one as the amount of production and demand does not warrant. A combination, or ring, control the whole supply, and keep the prices where they can make the most profit, Through the agency of Mr. Butterworth, the manager of the Almaden, a contract for the delivery of 50,000 flasks from the products of the mine prior to April 1, 1868, was made in 1866 with the late Mr. W. E. Barron for 30 dollars per flask. They obligated themselves not to sell or consign any quicksilver from the mine until the contract entered into was completed. Messrs. D. O. Mills and W. C. Ralston were Mr. Barron's securities for the faithful performance of his part of the contract, which was to advance 150,000 dollars on the debt of 250,000 of the company, and if necessary advance money to meet the full amount. The contracting parties found in April, 1868, that the production exceeded the demand, or rather that while the production was increasing the demand was the same, and declined to contract to purchase any more. However, another contract or agreement was made between Butterworth, representing the New Almaden, Barron and Mills, controlling the New Idria, and the owners of the Redington Mine for two years. By the terms of this contract as far as known, these mines were to limit their production to a certain amount, Barron and Co. were to be shipping and foreign agents, Redington and Co. local agents for the sale of the quicksilver here. The product of the mines was reduced, and by the arrangements made, the combination netted a profit of about 35 dollars per flask on the sales. The annual report of the New Almaden Company for 1870 states that the financial matters of the mine were in a bad state, and 55,000 dollars was required immediately to settle a lawsuit. There was also a large amount due to the bank of California. The agent, Mr. Butterworth, to get out of this financial difficulty, entered into contract with D. O. Mills to sell him the 15,525 flasks of quicksilver hitherto delivered to Barron and Co. under combination contract and all that would be delivered up to April, 1870, under said contract at 32 dollars in gold per flask. And all the product for two years from April, 1870, at 31 dollars gold per flask, half cash on delivery and half cash in 60 days, he discounting all deferred payments at current rates of interest if the company should so require. The company had the right to deliver an average of 2000 flasks of quicksilver monthly. He was to pay the company any sum that might arise after deducting amount due to Barron and Co. for advances on the quicksilver under their contract.

When the combination contract between the New Almaden, New Idria and the Redington Mines expired, the owners of the Redington, knowing that the two other mines were controlled by the same parties, declined to enter into any new combination or sell their product for the price which the New Almaden did. They finally entered into contract with Barron and Mills to sell their product for ten years. The price was not made public, but was generally understood to be forty dollars per flask, and the production was to be limited to a certain amount; Redington and Co., under this agreement, were still to have the local sale.

The Almaden Mine, in Spain, is entirely in the control of the Rothschilds, who have a lease of it. This mine supplies the London market and a large part of Europe and Mexico. California supplies the United States, China, and India, so the world is divided between the two great producers. An understanding exists between the two controlling parties which permits each to dispose of their quicksilver in their respective markets. The result is that a pound of quicksilver, owing to the duty of 15 per cent., is 15 per cent. dearer in California, where it is produced, than in Mexico, to which place it is exported from Spain.

By referring to the figures given above, it will be seen that the product of the several mines has gradually decreased since these combinations were formed. The consumption is, of course, limited, and an over supply would not suit the measures of the men who have control. Moreover, what is consumed would be consumed if it were 1 dollar or 1 dollar 50 cents per lb., just the same as at 85 cents; but small miners could not use it to advantage. The amount lost in amalgamating has been discussed at length in the *Scientific Press*. The Almaden ores just as they come from the mine would not average over 3 per cent. metal, and the Napa Mines not more than 1 per cent., so a good deal of ore is rejected; 3 per cent. ore, however, will pay well, and all of the mines would pay if they choose to sell at lower rates. Some of the mine owners, however, sell their product to the Bank of California combination, while others with small lots traffic with hardware dealers or others who supply parties in the interior. They generally undersell the combination a few cents, but the amounts are so small they make little difference. Although it is understood that the contract of this combination expired on the 1st of April of this year, their profit has been so immense that it is probable that there will be a renewal, and a combination of the various mines and interests will most probably be effected. So far as known at the present time, no such steps has yet been taken; but as prices remain as they have for months past, it is to be supposed that we shall have no reduction for some time to come. The owners of the Redington purposely keep down their product, because they prefer to keep the ore in the mine rather than sell it at the price agreed under a contract which only compels them to deliver what they manufacture. The only chance we should have to get a decrease in price would be in case a number of the new mines should refuse to enter the combination, and increase their product; but there is little chance of this. The ring have, too, a good thing of it, and doubtless intend to continue their operations on the old basis. Perhaps we ought, under the circumstances, to congratulate ourselves on being able to get it even at the advanced price we do. Still it seems lamentable that an article which is so indispensable to our mining operations should be subject to a speculative combination, without any conscience, as it depresses the leading industry of the coast. The miner requiring the use of quicksilver in California is obliged to pay the monopoly price, 85 cents per lb., while a merchant exporting pays but 80 to the same company for the same material.—*Scientific Press* (San Francisco).

EARLY CLOSING IN THE PROVINCES.

A Meeting of the Chemists of Loughborough was held on the 21st inst., and was the first of a series. The primary object was to take into consideration the desirability of a curtailment of the hours of business. All the members of the trade resident in the town were present, and they unanimously agreed to close their several places of business at eight o'clock in the evening (Saturdays excepted), when the hour was fixed at eleven o'clock.

Various trade matters were discussed, and general unanimity prevailed that the formation of an association would be advantageous; the lateness of the hour, however, prevented a definite decision, and the question was postponed to a future meeting, to be holden on the first Monday in August.

The Pharmaceutical Journal.

SATURDAY, JUNE 29, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE POSITION OF WIDOWS UNDER CLAUSE 16 OF THE PHARMACY ACT.

WE had thought, after the numerous explanations which have been given, in this Journal and otherwise, of the effect of Clause 16 of the Pharmacy Act, that at least its meaning was understood, and although there might be a disposition in some quarters to seek for an alteration of the law, for the sake of the relatives of those who might die without making the necessary arrangements for carrying on a business, we believed the possibility of such a provision and the nature of it were now pretty well known to the whole body of chemists and druggists. But the letter of Mr. BARKER, which is printed in another part of the Journal, and is only a type of many that we have received, appears to show that there is still considerable misapprehension upon the subject; and as it is a matter of very great interest to the majority of the members of the trade, we have thought it preferable to risk saying what has been said before if by so doing errors may be dissipated before they are irremediable.

The precise words of the portion of Clause 16 about which so much interest has centred, since the attention of the members of the Pharmaceutical Society present at the Annual Meeting was called to it by Mr. SMITH, are as follows:—"Upon the decease "of any Pharmaceutical Chemist or Chemist and "Druggist actually in business at the time of his "death, it shall be lawful for any executor, adminis- "trator or trustee of the estate of such Pharmaceu- "tical Chemist or Chemist and Druggist to continue "such business if and so long only as such business "shall be *bonâ fide* conducted by a duly qualified "assistant; and a duly qualified assistant, within "the meaning of this clause, shall be a Pharma- "ceutical Chemist or a Chemist and Druggist re- "gistered by the Registrar under the Pharmacy "Act or this Act."

In our opinion, upon the death of the proprietor of a chemist and druggist's business, the plan most judicious and profitable for all concerned is to realize the property on the most favourable terms that can be obtained, rather than carry on the business by a kind of proxy, with the possibility of its dwindling away. But those who differ from us in this opinion will see that the above words, read intelligently, provide for cases where it is wished to carry on a business, and certainly they are not open to the charge of inflecting hardship upon the survivors. If any hardship arises, it will be through the misapprehension or the neglect to act upon the provision therein made.

One principal danger seems to lie in the possible neglect of the fact that the power of an executor, administrator or trustee to carry on a business with the assistance of a duly qualified assistant exists only as long as the trust lasts, and that as soon as the trust ceases, such persons have no more right to carry on the business than any other unregistered person. As was clearly explained by the SOLICITOR at the last Annual Meeting, a business can "only "be carried on by trustees, or executors, or adminis- "trators, *not by a legatee.* If a man died without "a will, some one must administer in the estate, and "he could carry on the business for the benefit of "the widow; but the moment the estate passed to a "legatee, then the executorship or trusteeship came "to an end." With regard to the possible duration of a trust, he also explained that there was no limit "if and so long only, as such business shall be *bonâ "fide* conducted by a duly qualified assistant." Now, as it is possible to appoint any person a trustee on behalf of any other person, it is evident that any hardship that may arise will not *primâ facie* be caused by this clause.

Another point that must not be forgotten is the fact that the word "assistant" has a meaning attached to it in this instance very different to that with which it is unfortunately too often associated. As has been before pointed out, there is nothing in the law which prescribes the qualifications that must be possessed by an "assistant" to a registered chemist and druggist; this is at present left to his own judgment. But the "assistant" employed by an executor, administrator or trustee of an estate, must be a "pharmaceutical chemist" or a registered "chemist and druggist."

We have not alluded to this subject with any desire to promote the multiplication of such trusts as those above referred to. On the contrary, as we have before remarked, we believe that, as a rule, it is better that a business should be disposed of, while the associations of its former proprietor are fresh in the memory of the customers, than that they should be deadened by the intervention of one who cannot possibly take the same interest in it. But there is evidently a great deal of uneasiness, and perhaps some ill feeling existing among chemists and druggists, arising from a misunderstanding of the actual state of the law, and therefore any explanation that tends to remove it will have a worthy object in the promotion of peace and good will among the members of our body.

THE WATER FAMINE IN BERMONDSEY.

The dispute which has now for some time been raging, as to whether the water supplied to the metropolis is open to the charge of containing unoxidized recent sewage contamination, or whether the Government officials have been slandering good water and indulging in unnecessary indignation against the companies supplying it, has at least in one district been in abeyance during the recent hot weather; for in Bermondsey the people have been left almost without any supply at all, either good, bad or indifferent. Grimly satirical upon our boasted civilization is it that side by side with the newspaper accounts of the opening of a new museum for the special educational benefit of the "working man" in the east of London, we may read how his representative in the south of London has had to bring home the water for tea in a bottle from the factory where he works, or how he and his wife have had to wash for three days in the same water. And with such scarcity of supply for necessary wants of course such luxuries as baths and washhouses or the flushing of sewers are not to be thought of.

The want of interest that, spite of the new watchword, has been evidenced in the House of Commons about the progress of the Public Health Bills, may perhaps be partly attributed to a feeling that the creation of machinery for securing purity of water without a guarantee of the supply is, after all, putting the cart before the horse. Such a state of things would hardly be tolerated in an effete Eastern town; but the probability is that there the people would not be handed over to that modern invention for defying public opinion and sinking the individual conscience—a public company.

VIRES ACQUIRIT EUNDO.

From Clifton we hear that the members of the trade, with one exception, have joined in a notice to the public that on and after the 1st of July their shops will be closed for general business at 7 P.M. At Kilburn, the pharmacists have determined to act with those of St. John's Wood. And from Shepton Mallet we have received a circular, sent out by Mr. G. J. Cottrill, saying that as he does not keep an assistant he proposes to close at five o'clock on Wednesday afternoons.

Dr. Odling, F.R.S., the Fullerian Professor of Chemistry at the Royal Institution, has been elected Waynflete Professor of Chemistry in the University of Oxford, in the room of Sir Benjamin F. Brodie, F.R.S., resigned. Dr. Odling has also been elected a Fellow of Worcester College.

We learn from the 'British Medical Journal' that the Pharmaceutical Society of Lisbon has determined to hold an exhibition of Portuguese medicinal products, and that a committee has been appointed to arrange the time, place and other details.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 19th and 26th, 1872.

Thirteen candidates presented themselves for the Major Examination; of these, *five* failed. The following *eight* passed, and were declared duly qualified to be gistered as,—

PHARMACEUTICAL CHEMISTS.

*Townley, Thomas William	Ambleside.
*Jasper, Frederick William	Penzance.
*Shenstone, William Ashwell	Colchester.
Rammell, Edward	Crediton.
Warren, William	Chertsey.
Jameson, William Edward	Bristol.
Bouttell, Harold	Sudbury.
Bradford, Cordley	Spalding.

Forty-two candidates presented themselves for the Minor Examination; of these, *sixteen* failed. The following *twenty-six* passed, and were declared qualified to be registered as

CHEMISTS AND DRUGGISTS.

	*Watson, William	Chatham.
	*Perry, George Edward	Dudley.
	*Goldsmith, John Jackson	Abingdon.
	Cleaver, Edward Lawrance	London.
	Wheeler, Albert	Southsea.
	Dunston, Alfred	Spalding.
	Plummer, Arthur	Reading.
	Baynham, William Bevan	Bath.
	Sturton, Richard	Cambridge.
Equal.	Edwards, Charles	London.
Equal.	Jones, Owen Williams	Flint.
	Sherburn, Frederick	Keighley.
	Johnstone, William	Nottingham.
	Sangster, William	Islington.
	Jones, David	Rhyl.
	Colling, Robert	Stockton-on-Tees.
	Newton, Thornton Albert Claughton	Devonport.
	Brookes, Frederick James	Selby.
Equal.	Bell, Thomas	Harrogate.
Equal.	Cardell, Richard Taylor	Bodmin.
Equal.	Leake, Thomas Whaplate	London.
Equal.	Taylor, Henry Francis	Exeter.
	Thirlby, William Arthur	Ashby-de-la-Zouch.
	Atkinson, Miles Christopher	Manchester.
	Lewis, Edward	Sandown.
	France, Joseph	Rotherham.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned were received in lieu of this Examination:—

Certificates of the University of Cambridge.

Bayston, George	Guildford.
Izod, James	Sittingbourne.

Certificate of the University of Oxford.

Daves, William	Torquay.

Certificate of the University of Durham.

Barkas, Charles Edward	Newcastle-on-Tyne.

Certificates of the College of Preceptors.

Pearson, Thomas Styan	York.
Robinson, James Hedley	North Shields.

* Passed with Honours.

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The Third Annual Meeting of the Midland Counties Chemists' Association was held in their Rooms, 24, Quadrant Chambers, New Street, Birmingham, on Friday evening, May 31st, at 8 o'clock. Mr. Dymond, President, in the chair. The attendance of members was good.

The minutes of previous meeting having been read and confirmed, the following report was read by Mr. Lucas, Honorary Secretary.

Report.

"The Council of this Association is gratified in being able to issue a report this year of much encouragement.

"In their circular of July 10th, 1871, an endeavour to awaken a fresh interest in the objects of the Association was announced, to which a response of a most hopeful kind was made. The number of members, which, a year ago, was 102, is now (members and associates) 188, a large proportion of whom have been actively interested in the proceedings of the Association. The rooms in the Quadrant Chambers have been made good use of, the records showing that about 1600 visits have been made to the reading-room, exclusive of a large number of visitors who have omitted entering their names in the visitors' book. Of these, the associates (principally those who are engaged as assistants in business) form by far the larger part. It is this large and important class of chemists who must ultimately be the real gainers by the objects of the Association.

"The first meeting of the associates took place in October, at the invitation of the President, who supplied coffee and refreshments. The meeting was crowded, and it was certainly the largest assemblage of assistants ever held in Birmingham. Its principal object was to consider an educational scheme for the winter months. The scheme as proposed was adopted, and the names of about forty students who were desirous of attending classes and lectures were given in on the spot. The attendance at the classes did not ultimately keep up to the original number at the commencement of the session, reasons being found in the facts that some of the students left their situations and removed to a distance, and others having during the session passed through their troubles at Bloomsbury Square, felt the immediate pressure of the need of study removed. The lectures and classes were held in connection with the Birmingham and Midland Institute, the educational facilities of which are likely to prove of great advantage to the Association. To those students who joined the lectures in chemistry, the Professor of Chemistry, Mr. J. C. Woodward, gave special occasional lectures in the Pharmacopœia. The attendance at lectures on botany has been limited to ten persons. The Latin classes have assisted many to pass the Preliminary examination.

"During the year four evening meetings have been held, which have been well attended.

"At these meetings papers have been read as follows:—'The Examinations of the Pharmaceutical Society,' by William Southall; 'Volumetric Analysis,' by Henry W. Jones; 'The Study of Botany,' by J. B. Williams; and 'Disinfectants,' by Wentworth L. Scott, F.C.S.

"Amongst the other incidents of the past year may be noted a petition to Parliament, in June, praying for the suspension of any further legislative interference in the keeping and sale of poisons by chemists. It will be remembered that the Bill then before Parliament was afterwards withdrawn, and has not since been introduced.

"In the same month a grant of £10 was received from the Council of the Pharmaceutical Society, for the purchase of additional books for library. The secretaries were instructed at the same time to make application to the Free Libraries Committee of the Borough of Birmingham, for a restoration of the books committed to it in 1863, by the Birmingham Pharmaceutical Association, then expiring. This application was refused. In connection with the library, the council records its grateful thanks for many valuable presents thereto, amongst the rest, for some excellent pictures from Mr. Thomas Hyde Hills, for a clock from Mr. Edward Snape, and for a cabinet of materia medica specimens from Messrs. Evans, Sons and Co.

"The early closing of chemists' shops has obtained considerable attention; and an endeavour made during the year to secure an uniform hour for closing throughout the town of Birmingham, was not successful. The need of different districts of the town vary so considerably that it has appeared hopeless to expect all should combine in the observance of the same hour, but an agreed time, to suit the convenience of different districts has met with some success. This subject is likely to obtain further attention.

"The 'Price Book' of the Association has had a continued demand, the sale during the year being 149 copies, exclusive of copies supplied to members of the Association gratis. The Council cannot too earnestly commend to chemists the desirability, as far as practicable, of observing uniformity in the price of drugs, and particularly of medicines dispensed from prescriptions, and also of marking with the private mark of the Association all prescriptions when first compounded, that the first compounder of a prescription should invariably mark on it the price he has charged, with the private mark of the Association.

"On January 12th, 1872, a meeting of members of the trade was held in the rooms, to discuss the proposals made in this district by the Metropolitan Co-operative Association for the supply of drugs by chemists to its members. An unanimous feeling of opposition to this proposal was exhibited, and the signatures of a large number of chemists obtained, pledged to decline it. It was afterwards found that only one or two chemists in Birmingham remained under any engagement to the Co-operative Association, and its schemes, as far as chemists are concerned, practically fell through.

"The Council of this Association has also had the important subject of Provincial Pharmaceutical Education under its consideration, believing that great centres like Birmingham, have not yet obtained their due share of aid from the Central Council in London. A recent minute of the London Council, and an important movement of opinion among chemists throughout the country, gives the hope that this subject will, ere long, receive the attention it demands.

"The Council has sought to obtain for the Great Midland District, of which Birmingham is the centre, a representative at the Council Board in London; but, unfortunately, without success. It was hoped that the just claims of this district to a representative, and the personal character of Mr. John Churchill, would have secured his election. The Council suggest that it may be necessary to reform the present method of election, by which the representation of the chemists of the country is so unequally divided.

"Amongst the records of the year must not be omitted that of the *soirée*, which was given by the President on February 6th, 1872. Such a gathering of gentlemen and ladies interested in pharmacy had certainly never met in Birmingham before. It was attended by 240 persons. A great variety of scientific experiments and objects of interest were shown. Music was provided. The refreshment room was duly honoured with guests; and at half past ten, the floor being cleared, dancing commenced, and was continued till a late hour, every person agreeing that the evening had been most successful and enjoyable, and that it must be made an annual affair.

"The financial statement for the year is appended to this report, and shows a satisfactory balance in hand. This result, however, would not have been obtained without liberal donations, which it cannot be expected should be continued, and the Council conclude to ask the annual meeting to sanction a slightly increased annual subscription to meet the growing needs of the Association. As it is also not thought desirable that the cost of the winter *soirée* should in future devolve on the President, the subscription proposed is as follows:—For members, 7*s.* 6*d.* (or to admit to the *soirée*, 10*s.*); for associates, 3*s.* 6*d.* (or to admit to *soirée*, 5*s.*) each.

"In looking forward to the future of this Association, the Council is full of hope that the progress which has marked the past will continue, and that it will prove of real benefit to its members and others.

"Much yet remains to be done in the qualification of some of its members as members of the Pharmaceutical Society, and the Council invite chemists who have not yet done so to qualify themselves.

"The fee is a moderate one, and though the immediate results to the individual may not be perceptible, yet their general position in the advancement of pharmacy will have been thereby stengthened, and the coming generation will benefit by the advance (though it be small), which they have themselves made.

"It is believed that there is yet a considerable number of persons in the Midland District who vend poisons, who are not in the register of chemists and druggists. The Council wish to assist any legitimate chemists whose names may have been inadvertently omitted from the register, to obtain registration; but, at the same time, to protect the trade, by aiding in the prosecution of any others, who are neither entitled by the authorization of law, nor by their calling in business, to vend poisons; and they invite information of all such cases wherever they may be found in the Midland Counties.

"Donations of books for the library are earnestly desired.

"The attention of members and associates, and their friends, is again drawn to conveniences which the rooms of the Association provide.

"As a place of resort for trade meetings, the deposit of letters and parcels, letter writing for travellers, price lists, etc.; and as a house of call they are capable of much greater use besides affording opportunities for study to young men. The woman in attendance is prepared to receive miscellaneous work from chemists, such as pill making, powder folding, senna picking, and the thousand and one odd jobs of the shop, which she can perform at her place in the rooms, at a reasonable tariff of her own.

"STATEMENT OF ACCOUNTS.

From May, 1871, *to May*, 1872.

The adoption of this Report was moved by Mr. Churchill, seconded by Mr. Brassington, and carried.

The re-election of the President, Mr. G. Dymond, was moved by Mr. Arblaster, seconded by Mr. Churchill.

The re-election of the Treasurer, Mr. E. Snape, was moved by Mr. Churchill, seconded by Mr. Grieves.

The election of Messrs. W. R. Jones and F. G. Homer as Honorary Secretaries was moved by Mr. Brassington, seconded by Mr. Churchill, jun.

The election of Messrs. A. Southall and W. S. Akins as auditors was moved by Mr. Dymond, seconded by Mr. J. B. Williams.

The election of the following gentlemen to form th- Committee for the ensuing year was moved by Mr. Dye mond, seconded by Mr. Whittle, viz., Messrs. J. Churchill, H. Whittle, S. H. Morris, C. F. Palmer, T. Barclay, S. Dewson, G. Owen, J. Luca, W. Price, T. W. Holdsworth, Frobisher, Brassington, N. Mason, A. S. Grieves, H. Howes, and C. J. Arblaster.

The vote of thanks to retiring officers was moved by Mr. Brassington, seconded by Mr. Churchill All the resolutions were carried unanimously.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

At the rooms of this association, Royal Arcade, Newcastle, on Thursday evening, the 20th inst., Mr. R. D. Spence read a very interesting and instructive essay on "Some of the Crystals of the Pharmacopœia." There was a good muster of members, and Mr. B. S. Proctor, who was present, took an active part in the discussion which followed the essay; at the close of which both Mr. Spence and Mr. Proctor were awarded votes of thanks.

The Secretary, Mr. G. H. Proctor, called the attention of the members to a special subscription which was being raised to fit up a laboratory in connection with the association. Several gentlemen promised donations, amongst whom was Mr. Shaw, who also announced that he had received the promise of £1. 1*s.* 0*d.* from Mr. W. Herring, London.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

At the sitting of this Society on Wednesday, May 1st, under the presidency of M. Stanislas Martin, M. Lefort read a paper on "Belladonna," which he had studied with regard to the distribution of atropine in different parts of the plant,* and also as to the advantages that might result from the substitution of the leaves for the root in processes having for their object the extraction of that alkaloid. Describing in detail the mode of treatment which he applied to the leaves, M. Lefort insisted that the proportion of spirit really required is much less than that employed in the ordinary processes.

M. Boudet urged the importance that these researches presented at a time when alcohol is subjected to a heavy duty. Thus the process described by M. Lefort might have for a consequence the lessening of the cost of production of the alkaloids, and so bring back to the French laboratories the manufacture of those products, of which the origin is entirely French, but which are at present obtained in considerable quantities from other countries.

M. Duquesnel mentioned some considerations that led him to think that the employment of belladonna leaves in the fresh state for the extraction of atropine offered some advantages.

M. Lefort replied that he did not notice these advantages in his experiments, and that the employment of the fresh leaves would have the inconvenience of

* See *ante*, p. 1029.

limiting the time of manufacture to a small portion of the year. He added that he thought it of great importance that the École Supérieure de Pharmacie should exercise a careful supervision over the preparation of the alkaloids or active principles of plants, such as atropine, aconitine and digitaline, which under the form of granules or otherwise are met with so frequently in pharmacy, and which have the inconvenience of not possessing the desired uniformity, together with inexactness of dose, such granules and dragées not being generally prepared in pharmaceutical laboratories.

M. Mayet thought that it would be useful to call the attention of pharmacists and medical men to the danger that might result from the employment under the same name of very different substances, such as the digitaline of M. Nativelle compared with that of M. Homolle, and the aconitine of M. Duquesnel compared with that of M. Hottot.

M. Grassi showed the importance of this point by giving the details of a recent case of poisoning caused by the successive use in the making up of a prescription of amorphous aconitine and crystallized aconitine.

M. Roucher said that, besides the digitalines of M. Nativelle and M. Homolle, which differed from each other in many respects, there was the German digitaline, which, unlike both the others, did not sublime partially under the influence of heat.

M. Bussy considered that although these new products extracted from aconite and digitalis recommended themselves to the pharmaceutist by the characters of chemical purity and uniformity that they possessed, at present their medical action is not sufficiently determined to justify their substitution for the substances hitherto used in therapeutics. Until medical experience was more definite upon this point, the pharmacien should only use the substances prepared according to the Codex in the dispensing of prescriptions.

M. Poggiale thought that this question was of great interest; and even if it could only be decided by medical experience, the Society of Pharmacy could at least furnish the materials for this investigation by establishing the nature of the substances that should serve as a base, and by making a comparative study of their physical and chemical properties. While admitting that the Academy of Medicine had, according to law, the sole right to propose new formulæ, he did not think their society should, therefore, renounce the study of such questions as were of chemical and pharmaceutical interest. He proposed that a commission should be appointed to investigate the subject.

This proposition was agreed to; and the members nominated were MM. Bussy, Boudet, Grassi, Duquesnel, Lefort and Roucher.

M. Bussy gave a *résumé* of the sittings of the Academy of Sciences, and mentioned that M. Personne had recognized the presence of selenium in the sulphuric acid of commerce.

M. Duquesnel communicated the results of his observations upon sulphate of eserin (physostigmatin). Having noticed that a solution of this salt acquired a red colour in a short time, and apparently spontaneously, he sought if this alteration led to a weakening of the active properties of the medicament. The colouring matter, isolated by treatment succesively with potash and chloroform, had but little or no effect; from whence he infers that, if it represents, as he is led to believe it does, a product of oxidation of the eserin, the sulphate of that alkaloid will become less and less active as the solution becomes more and more coloured.

M. Desnoix presented to the society a duck's egg in which he had found two yolks, and which enclosed beside another egg, itself containing two yolks.

CHEMICAL SOCIETY.

Prof. Cannizzaro's Faraday Lecture.*

This lecture was delivered on May 30th, by Prof. Cannizzaro. The lectureship was founded by the Chemical Society in honour of the illustrious Faraday, to be held by some eminent foreign *savant*, who, during the term of his tenure, is to deliver a discourse before the Society. Dr. Frankland, in introducing the lecturer, said that in 1869 M. Dumas had honoured them with his presence there, and on that night they were to listen to Prof. Cannizzaro, of Palermo. After alluding to the numerous investigations which the Professor had made in organic chemistry, and amongst others the discovery of benzylic alcohol, the first normal aromatic alcohol that had ever been prepared, and to the important theoretical views which he had originated, the President, in the name of the Society, presented to him the Faraday Medal, struck in honour of his visit.

Prof. Cannizzaro said that when he received the flattering invitation to deliver the Faraday Lecture, he was placed in very unfavourable circumstances to respond to it, as he had no definite results to lay before the Society, and was, moreover, on the point of suspending his labours and abandoning his old laboratory in order to remove to Rome and establish a new one there. In this difficulty a subject for a discourse fortunately presented itself,—one which the celebrated French chemist Dumas had promised to treat of in 1847, namely, the form which the theory of chemistry should take at the present time. Although this could not be fully discussed in so short a space of time, it would at least have the advantage of directing the attention of chemists to a question of great importance in the transition stage which our science is at present going through.

In recalling the promise which M. Dumas had made to the Academy of Sciences of Paris in 1847, to examine the form which theoretical instruction in chemistry should take in the present state of the science, the lecturer proposed to consider in his discourse the limits within which the exposition of general theories should be included in teaching chemistry, and the form that it was desirable that they should assume. Whilst giving a broad sketch of the progress of modern chemistry, he showed that the atomic theory had become more and more intimately interlaced with the fabric of chemistry, so that it is no longer possible to separate them without rending the tissue, as it were, of the science; and that up to the present time we have been unable to enunciate even the empirical laws of chemical proportion independently of that theory; for those who employ the term equivalent in the sense that Wollaston did commit an anachronism. Consequently, in the exposition of the value and use of symbols, formulæ and chemical equations, not only are we unable to do without the atomic and molecular theory, but it is inconvenient to follow the long and fatiguing path of induction which leads up to it. By one of those bold flights of the human mind we can at once reach the height whence we discern at a glance the relations between facts.

He then went on to show that the solid basis, the corner-stone of the modern molecular and atomic theory, the crown of the edifice of which Dalton laid the foundation, is the theory of Avogadro and Ampère, König and Clausius, on the constitution of perfect gases, to which chemists, unknown to themselves, have been led in the progress of their science. He thought the time had arrived for reversing the order which had hitherto been followed in teaching chemistry, that instead of setting out from the criteria for determining the weight of molecules, and then showing their ratio to the vapour densities, they ought, on the contrary, to commence with the latter, with the theory of Avogadro and Clausius, demonstrating it from physical considerations; to found upon that the proof of the divisibility of simple bodies,—that is to say

* Reprinted from 'Nature,' June 20, 1872.

the existence of atoms; and to show, as occasion presented itself, that the weights of the molecules and the number of the atoms deduced by the application of this theory are in accordance with those which are deduced from chemical criteria. By this means we can measure the degree of confidence to be placed in the latter criteria; since so-called compound equivalents do not suffice to determine the weight of molecules, or even to prove their existence, although they may be deduced from a single principle, the theory of the constitution of gases. This is the natural transition from physics to chemistry.

The Professor then stated in detail how he applied the principles he had laid before them. He introduced his pupils to the study of chemistry by endeavouring to place them on the same level as the contemporaries of Lavoisier, and to teach them to appreciate the importance of the principle of the conservation of the weight of matter, showing them that this is quite independent of any idea of its nature or constitution. They are thus led to examine the ponderable composition of substances, so that the student passes rapidly from the epoch of Lavoisier to that of Proust, and then to that of Berzelius at the time when he commenced his researches on proportions. At this stage the same impulse is given to the pupil as Berzelius received on becoming acquainted with the hypothesis of Dalton. The latter is laid before him without any accessory, the use of symbols and formulæ being introduced dogmatically. There will now arise in his mind the same doubts and difficulties that assailed Berthollet, Sir Humphry Davy and Wollaston in the application of Dalton's theory, and at the same time a desire for an explanation of the simple relation which exists between the vapour volumes of bodies which react on one another, and of the products which are obtained. Now is the moment to state or recall to mind the physical theory of the constitution of the perfect gases. Commencing with a rapid glance at their general and special characters, he insisted that in this part of the instruction the mind of the student should not be diverted from the numbers expressing their relations by considerations of the variations caused by changes of temperature and pressure. In applying the theory of the constitution of gases, it will be perceived that the molecules of simple bodies are not always the atoms of Dalton, and a certain confusion will thus be produced in the mind of the beginner in the conception of the ideas of atoms and molecules. The hypothesis of Dalton can now be laid aside, substituting as a starting-point the theory of the relation of molecular weights to the vapour densities. A table must be prepared of the vapour density compared with that of hydrogen as 2; that is to say, the weights of their molecules compared with the weight of the semi-molecule of hydrogen taken as unity. We must then compare the composition of the molecules containing the same element (including or not the molecule of the element itself), and thence deduce the law of the existence of atoms,—that is to say, the amount of each element which always enters, by whole multiples, into the molecules which contain them. We here have the atoms of Dalton, which, in the present state of the science, express not only all that Dalton discovered, but also the composition of equal volumes of their vapours, and in the choice of which those doubts can no longer arise which embarrassed Davy and Wollaston. The ideas of molecules and atoms suggested to the student by this law are devoid of all considerations of form, size, continuity or discontinuity; the only property indissolubly connected with them is that of ponderability, the very definition of matter.

Recollecting that no physical theory of the constitution of matter had yet been advanced which thoroughly conformed to chemical ideas, he insisted upon the advisability in teaching the molecular and atomic theory, to keep it free from all that is not absolutely essential, so that it may preserve sufficient plasticity to adapt itself to the progress of our physical and mathematical knowledge. For this purpose he thought it useful to allow the student in the first place to glance at the changes in the hypothesis of the constitution of matter, and then to cause him to estimate the degree of confidence they merit in the actual state of our knowledge. Having thus placed upon a solid basis the fundamental notions of atoms and molecules by the comparison of the composition of equal volumes of the bodies in the gaseous state, it becomes necessary to consider the difficulties which arise in the application of these notions when the vapour densities are wanting; he explained and justified the use of the various auxiliary criteria to which we have resource in these cases, proving them in the first instance by the touchstone of the theory of Avogadro and Clausius, by showing that they gave results in accordance with that theory whenever the two methods can be employed simultaneously.

He believed that we should never lose sight of the starting point, nor give the formulæ of all compounds as of equal probability. "It is not by concealing the obscurity of these questions that we shall enlighten the student; on the contrary, we should estimate each fact at its true value by showing him that our science does not merit an equal degree of confidence on all points." This forms the introduction, the preparation for the study of the transformations which matter undergoes; the real object and aim of our science.

The comparison of the atomic composition of molecules has led chemists to the law of substitution, to the theory of types of Dumas, then to that of Williamson and Gerhardt, and lastly to the theory of the different valency of atoms and their modes of union, or the so-called theory of atomicity which includes the former. Although at present it is impossible, in teaching chemistry, entirely to eliminate this latter theory, which gives a summary of several laws, and guides us ordinarily in the co-ordination and even prevision of a large number of facts, yet it is difficult to keep it within just bounds so as to avoid infusing into the mind of the beginner illusions which are dangerous for his intellectual education. In order to avoid this, it is advisable to bear in mind the progress of this doctrine and the actual phase of development which it has at present reached. It is still far from being a complete and well-established theory, but is in a state of transition; for although doubtless it embraces a large number of facts, as yet it does not embrace them all. It is only a partial representation of the reality, and that from a restricted point of view, showing but little relation to our views of the constitution of matter, for it is the result of a comparison of diverse facts expressed by means of the atomic and molecular theory. It is convenient, therefore, to consider each part of this doctrine exclusively in relation to the group of facts which has suggested it.

It is unadvisable to define the valency of atoms as a property inherent in them, and then to deduce as a corollary their different modes of union; on the contrary, it is preferable to regard each portion of this doctrine as a deduction from the observation and comparison of a determinate group of facts, until an opportunity offers to unite these fragments into one whole, not forgetting, however, to notice the gaps which exists, never going beyond what the facts themselves suggest, and never applying to all bodies indiscriminately, the laws which suit only a single group. For instance, we must not pass over in silence the facts that whilst certain elements are bi- tetra- or even hexa-valent, others are tri- and penta-valent; but the pupil should be prevented from acquiring mechanical and geometrical ideas of the cause and effects of the valency of atoms, by frequently reminding him that chemical facts show nothing about the size, form, continuity, or relative position of atoms. If we are sometimes obliged to employ the expression, "relative position of atoms in the molecules," and even to represent them graphically, we must warn the student that these are only artifices to express certain transformations, and that we are really ignorant of the relative position of the atoms either in space or in the mutual action of different portions of matter. With these reservations, it is possible, in teaching to derive considerable advantage from the theory of atomicity, and at the same time to avoid its inconveniences.

In the study of the transformations which matter undergoes, we should direct the pupil's attention, not only to the ponderable changes in the composition of molecules, but also to the electrical and calorific phenomena which accompany these transformations. Even from Lavoisier's time it has been recognized that we cannot separate the study of matter from thermic considerations; and every day the connection which exists between chemical and thermic phenomena becomes more apparent.

As in the study of ponderable changes we were guided by the law of the conservation of weight, so in the connection between chemical and dynamical phenomena we are guided by the law of the conservation of force; the two studies mutually supplementing and illustrating one another. Not only will the atomic and molecular theory and that of atomicity help us to compare dynamical phenomena, but the study of dynamical phenomena will show us analogies and differences between chemical actions which would not be observed in the ponderable equations. We should therefore instruct the student in the little definite knowledge which we at present possess concerning thermic and electric phenomena, and especially fix in his mind the fundamental notion of a mechanical equivalent, and the manner of comparing it with chemical action as expressed by the atomic theory. In this we should be aided by the previous or simultaneous instruction of the student in physics under the form and language of the thermodynamic theory.

The lecturer concluded by observing that in the choice of methods and of matter for a course of chemistry, it should always be borne in mind that it was eminently a progressive science, and that even at the time of its most rapid development. The student should start not only with a knowledge of certain definite and fixed principles, but with an apitude and sufficient preparation to enable him to follow the science in its unceasing transformation and progress, whether he intends expressly to cultivate chemistry, or has only learnt the elements of the science as an auxiliary to other studies or professions. Moreover, the end of chemical instruction for both these classes of students is not only to fix in their memory a certain amount of knowledge, but to assist in their intellectual education. For this, chemistry of all sciences is one of the best, offering both in verbal and practical instruction—excellent occasions for the exercise and harmonious development of all the faculties of the human mind.

He had desired to call attention to what he considered to be the most efficient means of imparting a knowledge of chemistry so that it might serve as an instrument of intellectual education, and that the student, by following it in its ulterior developments, might judiciously apply it to the study of the other branches of natural science. If the attention of the eminent chemists and professors there present were once attracted to this subject, he felt certain that a bright light would be thrown on it, and that our young professors would find numerous suggestions to direct them in teaching chemistry, and that at the very moment when instruction in our science had become so difficult on account of the rapid transformation which it was undergoing.

Dr. Williamson said, that those who were there present ought not to separate without some expression of the pleasure that they had felt on listening to so learned, vast, and eloquent a discourse, treating as it did of a most difficult and important problem. There was scarcely anything of greater moment in the scientific education of youth than the rightly setting before them those wonderful transformations of matter which it is the province of chemistry to explain. These great and growing truths, for, as the lecturer had said, they were growing truths, should be set before youth in such a manner as to form a coherent whole. He hoped to study this masterly discourse with profit and delight, and would now propose a vote of thanks to his illustrious colleague for the honour which he had done them in delivering to them the Faraday lecture.

Professor Tyndall said he had heard the discourse with deep interest, for it showed that the lecturer knew the importance of a teacher's vocation, and that his province was not merely to communicate knowledge, but to do it in such a manner as to arouse an interest in and love of the subject in the pupil by presenting it in its proper relations. He would have welcomed the lecturer to that Institution, even had he come to tear in pieces the notions which he cherished regarding atoms and molecules; how pleasant it was then to find such a broad agreement between their views. The chemist cannot halt at equivalent proportions—he must ask himself whence they arise, and the inevitable answer is some form of the atomic theory. This theory, however, cannot be confined to chemical phenomena. The motions of those atoms and molecules underlie all our explanations of the physical cause of light and heat, and it is already taking up the field of magnetism and electricity. Consider, for example, the heat of gases, both as regards the motion of translation of the molecules which produce temperature, and the motions of rotation and vibration of their constituent atoms, which, though they do not express themselves as temperature, constitute a portion of the heat. Clausius has shown that even in the simplest gases nearly two-fifths of the whole heat is due to these internal motions; while in gases of complex molecular constitution which condense on combining, the ratio of the total heat to the heat of temperature is still greater. The experiments of Regnault, which show that the specific heat of a perfect gas at a constant volume is constant, proves, as Clausius has shown, that the one kind of motion is proportional to the others.

The lecturer had also referred to atoms of the same kind combining together, so that, free oxygen and free hydrogen being considered as composed of molecules, each containing a pair of atoms, has certainly simplified the results. But it must not be forgotten that this combination of like atoms is widely different from that of unlike atoms. The union of oxygen with oxygen or nitrogen with nitrogen produces no such effects upon the luminiferous ether as the union of oxygen with nitrogen. With the same quantity of matter the amount of *vis viva* sent forth as radiant heat may be augmented a thousandfold, perhaps a millionfold, by the act of diverse combination. This act seems to carry with it a condensation of the ether to a dense atmosphere around the atoms. Had a cannon the power of gathering round itself a dense atmosphere, it would send forth a greater amount of *vis viva* as sound. A gun fired at Chamouni may be heard upon Mont Blanc, while the same gun fired on Mont Blanc may not be heard at Chamouni, because the air on which the concussion takes place is denser in the one case than in the other. In the same way the diverse atoms vibrating in the denser atmosphere formed on combination show their vast superiority as radiators over like atoms which, except in such special cases as ozone, etc., are incompetent to produce a similar condensation. The speaker then asked them to echo the resolution so well put to the meeting by Prof. Williamson.

Thursday, 20th June, 1872; Dr. Frankland, F.R.S., President, in the chair.

After the usual business of the society had been transacted, the President announced that Mr. Hyde Hills had given ten guineas to the fund for promoting original research, and promised to further increase his donation by ten guineas for each ninety subscribed for the same purpose.

Mr. H. Deacon then delivered his lecture "On Deacon's method of obtaining chlorine, as illustrating some principles of Chemical Dynamics." The process consists in passing a heated mixture of air and hydrochloric acid over sulphate of copper or over pieces of pumice or brick saturated with the same. He finds that the action is essentially a surface action, and that there is a certain comparatively small range of temperature between the critical limits of which the percentage of hydrochloric acid decomposed varies greatly. The velocity with which the mixed gases pass over the surface of the active material also causes considerable variation in the comparative amount of chlorine produced.

After a vote of thanks to the lecturer, the meeting adjourned over the recess.

Parliamentary and Law Proceedings.

PAPERS PRESENTED TO PARLIAMENT.

Second Annual Report of the Deputy-Master of the Mint.

The Report of Mr C. W. Fremantle, Deputy-Master of the Mint, concerning the operations in that establishment during the year 1871 has just been issued. The amount of gold coinage executed was far above the yearly average, which is about 5,000,000. But so extraordinary was the demand for gold coin which characterized last year that £9,798,735 was struck during that time, of which no less than £5,748,200 in sovereigns and £140,000 in half-sovereigns were coined and delivered between the 25th of September and the 20th of December.

The coins struck during the year were of four metals,—gold, silver, bronze and nickel, the last being pence and halfpence for use in Jamaica. The total number of pieces was 30,022,404, and their value, real or nominal, £10,580,061 11*s.* 5*d.* Of British coins there were sovereigns and half-sovereigns in gold, florins, shillings, sixpences and threepences in silver; and pence and halfpence in bronze. Besides these there were fourpences, twopences and pence in silver, sufficient for "Maunday money only." It will not be out of place here to remark that the issue of crowns and half-crowns has been suspended since 1851, and that of groats or fourpenny-pieces since 1856.

With reference to the first two of these coins a point is under consideration that marks the progress that has been made during late years in metallurgy. As is well-known, silver when extracted from its ores usually contains a small quantity of gold; but the process of refining as practised when the coins in question were struck was too expensive to admit of the extraction at a profit of the small quantity contained in them. At the present day, however, improvements in refining render it possible to extract with profit any quantity of gold exceeding two grains in the pound troy of silver. Samples examined in the Mint prove that the half-crowns now in process of withdrawal contain an average of 4·07 grains in the pound, and when therefore any considerable quantity of these coins has accumulated in the Mint, it will probably be advisable to recommend that the gold should be extracted from them before they are re-coined. So long ago as 1831 this subject was alluded to before a Parliamentary Committee by Mr. Mathison, the officer then in charge of the refinery at the Mint, and an opinion was expressed by him that the extraction of gold from the worn silver coin melted during the year would have been attended with an actual profit of £1412 to the public.

The work in the melting-house is frequently prolonged by the steps which must, in many cases, be taken for recovering, before the daily account can be balanced, the portions of metal which may have remained in the crucibles, or have been unavoidably spilt during the crack of the bars. [In the uncertainty which at present prevails as to the removal of the Mint to a new site, it has not been considered advisable to take steps for replacing the melting furnaces now in use by those in which gas would be used as fuel; but sketches have been made by the chemist of the Mint of gas furnaces actually in use elsewhere, and the consideration of the question will be resumed whenever the opportunity may arise.

In a memorandum by Mr. Hill, the Superintendent of the Operative Department, he states that the benefits derived from the introduction of plumbago crucibles for silver melting have been most marked, and he adds that they are not only better and cleaner, but also considerably cheaper than the iron pots formerly in use, and that the out-turn of each day's work is far more satisfactory. The old crucibles are ground up in the same manner as those that have been used for gold-melting, and the "sweep" is washed so as to obtain as much silver from it as possible, and is afterwards dried and sold.

With regard to this "sweep," it may be stated that hitherto it has been the practice to grind the crucibles, ashes, etc., and to sell by tender such portions as pass through a sieve of forty meshes to the inch. With a view to ascertain whether it was desirable to continue the above-mentioned practice, or to undertake as an operation of the Mint the extraction of the precious metals from the "sweep," Mr. Roberts, the chemist of the Mint, made a series of assays, but arrived at the conclusion that comparatively small quantity resulting from a coinage of average amount could not be treated with profit to the department.

The actual deficiency of metal at the close of the gold coinage in June last was found to be 402,728 ounces, the value of which in money was £1568 2*s.* 5*d.*, or £241 per million. The greater part of this deficient metal having been recovered by the sale of the "sweep" for £1240 13*s.* 4*d.*, the actual loss of the Mint on the coinage was proved to be £327 9*s.* 1*d.*, or £50 per million. In this waste on the coinage of gold is included the loss attending the reception of light gold for re-coinage. This loss is due to two causes: (1) that a certain amount of dirt always adheres to the surface of the coins, the weight of which disappears in melting, and (2) that although received as standard gold, the light coins at present in circulation are found to be in reality below the exact standard of fineness, and to require the admixture of a certain proportion of fine gold before they can be again converted into coin.

The method which has been recently introduced of toughening brittle gold by means of a current of chlorine gas is reported upon very favourably. Brittleness in gold is usually due to the presence of minute traces of foreign metals, and these metallic impurities are eliminated as chlorides by the passage of chlorine gas through the molten metal. The amount of gold set aside as unfit for working during the coinage of £6,500,000, which was completed in July, 1871, amounted to 40,000 ounces. In the melting of gold, as ordinarily practised in the Mint, crucibles of graphite are employed, but such crucibles are not well adapted for use in the treatment of gold by chlorine gas, as the gases evolved from them exercise a reducing action upon the chlorides. It therefore has been fouud advisable to substitute crucibles of fire-clay for those of graphite.

About 1100 ounces of gold are melted in each crucible, and the chlorine gas is pasaed through each in succession, the time during which the metal is exposed to the gas varying from five to seven minutes. The gold is found to be perfectly tough, and is re-assayed and again melted with the amount of copper required to form standard gold.

The following statement indicates the result of the operations upon 40,000·000 ounces of standard gold.

	oz.	oz.
Amount of initial loss		40·360
Amount of gold recovered from ground-up crucibles, borax, etc.	15·507	
Amount of copper and base metal proved by assay to have been eliminated as chloride	27·746	40·253
	Loss	·107

It will be seen that the loss on toughening 40,000 ounces was only one-tenth of an ounce, and the process may now be considered to have fairly taken its place as an operation of minting.

The accuracy of the automatic weighing machines, in which each piece of gold and silver is weighed before it is issued, has, during the large coinages of the year, been severely tested, and, owing to the rapid execution of the work in the rolling and adjusting rooms, and the increased liability to error consequent upon it, additional care has been necessary in the weighing-room to prevent the issue of coins not within the remedy of weight prescribed by law. It is necessary in weighing coins to use a still smaller remedy than that which the law allows; and it may serve to give some idea of the delicate nature of the work performed by these machines if it be stated that the 100th part of a grain is sufficient to cause a sensible deflection of the beam, and that the weight which denotes whether a sovereign is or is not within the remedy is represented by a piece of wire of fine gold, 0·1355 of an inch in length, and 0·018 of an inch in diameter, and weighing 0·17 of a grain.

On the completion of the last gold coinage, which amounted to £6,500,000, it was found that the aggregate weight of the pieces corresponded precisely with the standard weight prescribed by law. Such exactitude it is believed, has never been attained before on so large a coinage; but it should be remarked that so close an agreement with the standard weight depended upon conditions which cannot always be secured.

During the year 1871, the staff has been increased by the appointment of "balance mechanician," to undertake the repairs and adjustant of scales and weights; work hitherto performed by private firms.

The abolition of the office of non-resident assayers, and the return to the ancient system under which all bars when allowed and melted in readiness for coinage, and coins selected from all the coined work, were assayed within the mint itself, is reported to have been attended with most satisfactory results, it having rendered possible the exercise of a more direct and efficient control than heretofore over many details upon which the accuracy of coining in a great measure depended, and materially contributed to a more rapid execution of the coinage. But in order to provide for a portion of the duties formerly performed by the non-resident assayers, namely that of determining questions that might arise between the Master of the Mint and importers of bullion for coinage as to the correctness of assay reports, a Consulting Assayer to the Mint has been appointed in the person of Dr. John Percy, F.R.S. In the new assay office the volumetrical method of assaying silver has been introduced, and it has been found that the method is peculiarly well adapted for the verification of the composition of silver alloys which vary little in fineness.

The most important which have taken place during the year 1871 in the coinages of European countries, has been the introduction of a new coinage of gold into the currency of Germany, as a preliminary step to the option of gold as the single standard of value. It is satisfactory to note the steps taken by the German Government, namely, the introduction of a gold standard, and the establishment of a uniform coinage based on the decimal system, throughout the Empire; but it is to be regretted that a coinage has been adopted which in one important particular at least is open to serious objection, and may give rise to some difficulty. In the discussions which have taken place during late years, it has been shown that there are several gold coins in Europe and the United States of America, either already issued, or proposed to be issued, which contain a nearly identical quantity of pure gold, namely,—

Half-eagle or 5-dollar piece (United States)	7·52 grms.
Sovereign (England)	7·32 „
25-Franc piece (proposed for France, and the States associated with her in the Monetary Convention of 1865.)	7·26 „

In addition to these the Spanish Government has proposed to coin a piece of 25 pesetas, of equal value with the 25-franc piece. To these coins, however, recent legislation in Germany has added the 20-mark piece, containing 7·16 grms. of pure gold, and equal in English money to not more than nineteen shillings and sevenpence, the issue of which creates a further divergence from that uniformity which is so much to be desired, and forms an additional obstacle to the adoption of an international gold coin.

In the die department amongst the new designs must be noticed the sovereign bearing the reverse of St. George and the Dragon, which, having been authorized by Order in Council, has been issued concurrently with those of the design already in use during the present reign. The Mint has also been called upon to furnish a medal to be awarded annually to the best shot in the infantry of the army, which will shortly be issued.

In concluding the report, allusion is made to the proposed change of site for the Mint. It is stated that the works of the Mint are in no way of a nature to create a nuisance to a neighbourhood, no refinery being now attached to the department. Only refined metals are melted, in the fusion of which no acid is employed, and any fear that the processes carried on might be injurious to health are said to be without foundation.

Poisoning by Water Hemlock.

On Monday afternoon the coroner, Mr. Tatlock, held an inquest at the Turf Tavern, Chester, on the bodies of two boys, inmates of the Workhouse, named George Dobson and Albert Kinsey, who met their deaths on Sunday by eating what they supposed to be wild celery, but which was in reality water hemlock. From the evidence it appeared that the schoolmaster took the boys out for a walk on the Roodee after morning service, and, having proceeded with them as far as the railway arches which span the river Dee, told them they might amuse themselves till they were called, and then returned to the Workhouse. The boy Dobson, who had been in the same place on the previous Tuesday eating the roots of the plant, and who had suffered most severely in consequence, persuaded the other boy to go down to the edge of the river to gather some of the "wild celery," which they did, and having filled their pockets returned to the yard of the Workhouse, where they freely indulged. The roots, according to the evidence of Dr. Britain, have the taste of soft cocoanuts, are quite palatable, but are most dire in their effects. Shortly after eating them the boys became extremely ill. The doctor was sent for, and he at once administered an emetic of mustard and hot water, which took effect on all except the two deceased boys, to whom it was impossible to administer any in consequence of their suffering from severe convulsions, and their teeth being tightly clenched. He, however, applied turpentine externally, but without avail, and the boys died most agonizing deaths. The jury returned a verdict of died from the effects of eating water hemlock.—*Liverpool Daily Post.*

The Pharmacy Act and the Sale of Homœopathic Medicines.

Sir,—Permit me to avail myself of your columns to inquire of those of my brethren skilful in interpreting the Pharmacy Act "whether *homœopathic* chemists may legally keep open shop for the dispensing of physicians' prescriptions and the sale of poisons without being on the register of the Pharmaceutical Society?" and, if not, why have they been treated with such considerate tenderness by the officials of the Society?

I am myself under the impression that the Act applies to homœopathic quite as fully as to allopathic chemists; indeed, if such be not the case, any person desirous of entering the sacred precincts of pharmacy without passing through the legitimate but tedious path of the examinations, may easily do so, and entirely evade the Act by placing the adjective 'homœopathic' before his assumed title of chemist, and exhibiting in his shop some pilules, globules, a few bottles of arnica, strong solution of camphor, etc. But having reported to the Society, a considerable time ago, what appeared to me to be a most flagrant case without their taking any decisive action therein, I presume the possibility of my opinion being erroneous, and think it desirable to bring the subject before the notice of the trade, as it undoubtedly affects all pharmacists in no small degree, and should, I think, be no longer overlooked by the Society's executive.

The popular notion of the trade of a homœopathic chemist is that it is confined to supplying drugs (poisonous or otherwise) in doses so infinitesimal as to possess no more therapeutic activity than Sac. Lactis or Sp. Vini Rect. That this is an erroneous notion, fifteen years' experience of homœopathy enables me to prove. In the first place, it is by no means an uncommon occurrence to retail the mother tinctures of aconite, belladonna, nux vomica, etc., prepared in the proportions of 1 to 10, as directed by the British Homœopathic Pharmacopœia, or the first or second decimal of arsenicum, morphia, antim. tart. and other potent medicines; and, secondly, it is a portion of almost every day's work to dispense prescriptions for liniments or applications containing chloroform, aconite, and belladonna liniments, or tinct. opium, etc., in sufficient quantity to poison very many people.

The following are copies of prescriptions written by a homœopathic physician in large practice, and who invariably directs his patients to have their medicine prepared by a certain homœopathic chemist, who has passed no examination, is not on the register, and who, therefore, in vending poisons and preparing prescriptions, is surely violating the very letter of the Pharmacy Act; yet it is against such an offender that the Society declines to take proceedings.

℞. Trit. Podolph. Resin 1* gr. xij.
Divide in pulv. vj cujus j bis in hebdomadâ sum.

℞. Liq. Arsenic. Fowler. ʒ ij.
Aq. Dest. ad ℥ iv.
Misc. Cap. ʒ j ter die.

Divide Trit. Morph. Hydroch. 2 x gr. 100 in pulv. æq. x. Cap. j ex aquâ coch. amp. omni nocte et repet. post horas quatuer si opus sit.

℞. Lin. Belladon. P. B., ℥ iij.
Chloroform, ℥ j.
M. ft. lin. more dict. utend.

℞. Kali. Brom. gr. 80.
Aq. Dest. ad ℥ iv.
M. Cap. ℥ ss. ex aqua bis die.

Is it not decidedly unfair that those of us who have given both time and money to procure the requisite qualifications for business, should find ourselves opposed by persons possessing no legal title whatever, whilst a great and wealthy Society, supposed to keep a sharp eye on such offenders, stands coldly aloof and declines to protect the interest of its members?

A Chemist.

Position of Widows under Clause 16 of the Pharmacy Act.

Sir,—Without wishing to make special reference to the particular case to which Mr. Smith alludes, may I ask you to give information to prevent the repetition of so sad a calamity.

If a chemist makes his will and leaves his wife executrix, jointly with a (male) friend, can he (if not a chemist) carry on the business, with a qualified assistant for her benefit and that of her family?

As I, with many others, have been toiling on for many years, I should deeply regret if, through any act of inadvertence on our part, our wives or children were deprived of the fruits of our industry and application.

Joseph Barker.

Kingston-on-Thames, June 15th, 1872.

Chemical and Pharmaceutical Curiosities of a Medical Practitioner.

Sir,—Would you kindly give the following a place in your Journal, for the amusement of all interested. Some time ago the following prescription was brought to me to make up:—

℞. Col. 2 . . . ʒ ij.
Ol. Olive . . ℥ ij. M.
Sig. Use as directed.—G. G.

Not knowing any chemical compound under such a symbol, I at once communicated with the writer, but got no answer; during the forenoon of the following day, the following was brought in its stead by the same customer:—

℞. Acid Carbol. . . ʒ ij.
Ol. Olive . . ℥ ij. M.
Sig. Use as directed.—G. G.

The other day I again received the following rather obscure prescription:—

℞. Saponis cum pici. . ℥ ij.
Sig. For external use.—G. G.

There being no official preparation of this kind in the P.B. or any other Pharmacopœia that I knew, I at once wrote to him for information about it, but whether he is ashamed of his ignorance, or what, I know not, but he has not yet replied, and the prescription remains with me undispensed.

G. H.

June 18th, 1872.

W. Dixon.—We will endeavour to obtain the information asked for by you.

G. Broom.—A communication that we have received through the publishers bearing the above signature, appears to be a *résumé* of what has recently appeared in the medical papers on the subject. The subject, however, is too purely a medical one, to be suited for our columns.

"*A Registered Student of the Society.*"—Your question shall be answered next week.

G. C. Cottrill.—We beg to acknowledge your communication, and think your resolution a very wise one.

"*Pharmacien,*" "*An Apprentice of the Pharmaceutical Society,*" and *E. W. B.*, are all referred to the rule as to anonymous communications.

"*Nemo.*"—(1 and 2.) Yes. (3.) We think such sales in wholesale quantities, and under the regulations prescribed by clause 17 of the Pharmacy Act and the Arsenic Act, would not be construed as being an infringement of the Act.

"*One who has known the Drug more than Thirty Years.*"—Thanks for your cutting. It does not look healthy, and we regret to see it.

The following journals have been received:—The 'British Medical Journal,' June 22; the 'Medical Times and Gazette, June 22; the 'Lancet,' June 22; the 'Medical Press and Circular, June 22; 'Nature,' June 22; the 'Chemical News,' June 22; 'English Mechanic,' June 22; 'Gardeners' Chronicle,' June 22; the 'Grocer,' June 22; the 'Journal of the Society of Arts,' June 22; 'Grocery News,' June 22; 'American Chemist' for May; 'Practitioner' for June; the 'Madras Monthly Journal of Medical Science' for May; 'New York Druggists' Circular' for June; 'American Journal of Pharmacy' for June; the 'Western Lancet' for April; the 'Pharmacist' for May; the 'Devonport Independent,' June 22.

Communications, Letters, etc., have been received from Mr. J. Paget, Messrs. Thorne Bros., Mr. Nuthall, A. P. S. 'Mel.'

INDEX TO VOL. II.

(THIRD SERIES.)

All Letters to the Editor will be found arranged under the head of "Correspondence;" Leading Articles, etc., under the head of "Editorial Articles and Notes."
